Dr. W. B WARRINGTON described a rare form of Muscular Atrophy, known in this country as the hereditary type of peroneal atrophy first described by H. Tooth and Charcot and Marie. He pointed out the characteristic features of this affection—viz, an atrophy beginning in the muscles of the outside of the leg and then invading the small muscles of the hand The knee jerks were absent and the electrical reactions were peculiar inasmuch as muscles which were capable of good voluntary movement could be stimulated only by very strong currents and then they only reacted feebly. Dr. Warrington discussed the literature of the subject, especially the papers by Hoffmann and Bernhardt, and pointed out that when dealing with hereditary nervous affection the symptomatology tended to extend beyond the well defined lines of the classical description —Mr ROBERT JONES remarked on the surgical treatment of this case of Tooth's paralysis which he had had under his care. Both feet were affected, the left being the worst. The foot was in equino varus with limitations of ankle movement and a general rigidity [illegible] paralytic type There [illegible] the joints of the foot [illegible] contraction of the plantar fascia. No spasm was present, but there was contracture of tendons The tibialis posticus, the tendo Achillis, and the extensors of the toes and the deep ligaments of the sole were divided, and the foot was forcibly wrenched into position. The left foot gave great trouble from a sharp flexion angle formed by the metatarso phalangeal row on the plantar aspect, and was treated by ex section of each prominent phalangeal base The patient now walked quite comfortably —Dr. BRADSHAW said that the family history did not seem to support the view that the different developmental neuropathies merged into each other, but the contrary. A family affected by the peroneal type of paralysis was not affected by Friedreich's ataxia, and vice versa The hereditary weakness appeared to be inherent in certain tracts of the central nervous system and not in that system as a whole.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.

THE seventh ordinary meeting of this society was held on May 1st, Dr. A. G MILLER, the President, being in the chair.

Dr NORMAN WALKER showed a case of Bazin's Disease in a girl, aged 16 years, who came to the infirmary about eight weeks before with an eruption on one leg extending up to the waist and looking something like ecthyma The lesions were deeper, however, and had a more chronic appearance than the lesions of that disease and all cultivations from them proved to be sterile (unlike ecthyma) The patient had markedly enlarged cervical glands and some dulness at one apex with cough and expectoration. The case at that stage was the first definite example which he had seen of the condition described by Kaposi as acne scrofulosorum During her stay in hospital there was no great improvement, but soon after she went home the condition got much worse and she returned with the lesions advanced and the condition now closely resembled that known as Bazin's disease.

Dr. WALKER also showed two other cases which he exhibited mainly for the interest attached to their treatment. The first was a case of Lupus of very extensive distribution. This had been over the face treated for the past five months with weekly applications of the x rays, the exposures latterly lasting for 20 minutes The patient was far from well, but the improvement was very marked and the increase in comfort was alone worth the trouble A peculiarity which he had noted in connexion with the treatment of such cases by the x rays was shown in this patient—namely, that the disease had improved to a greater extent behind the neck than in the front, though the rays were only used in front. The rays seemed to be more active at their points of emergence than at their entrance and their application was absolutely painless and gave rise to no ulceration. During a recent visit to the London Hospital, where he had had an opportunity of seeing both varieties of the light treatment, Dr. Walker was greatly impressed by the success attendant on the much less advertised x ray treatment. While there on a previous occasion he had seen a further use of the rays in connexion with the treatment of rodent ulcer the results of which were so good that it was almost necessary to see to believe. Large cavities occupied by inoperable cancers had filled up and healed with a smooth scar. The treatment had been commenced on two of Dr. Allan Jamieson's patients, and he showed one of them (a man) who had had six exposures to the rays and already the ulceration had greatly improved.

Mr. SHAW M'LAREN demonstrated Schlangintweit's Cystoscope and showed the advantages which this instrument possessed over other similar varieties

Dr T. V. PATERSON showed a most instructive series of sections through Diseased Eyeballs mounted in Gelatin. He also showed a large number of lantern slides illustrating Eye Diseases

Dr. WILLIAM RUSSELL read a paper on Arterial Hypertonus and Arterio sclerosis, their Relations and Significance, with a lantern and microscopic demonstration. The paper will be published in our columns shortly.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

Mortality of Infants from Improper Feeding —Tuberculosis in Cattle.

A MEETING of this section was held on April 26th, Sir C. A CAMERON, the President, being in the chair.

Mr. GEORGE P COPE read a paper on the Mortality of Infants under One Year from Improper or Imperfect Feeding, with Suggestions for Public Instruction to Parents and Nurses on the subject, enumerating a list of diseases, together with the number of deaths caused by the same (made out from the Registrar General's returns of registered deaths in Ireland for the years 1890 to 1899) which could be considered to be directly or indirectly due to improper feeding. For the last five years—1895 to 1899—there was an increase of 2188 deaths compared with the previous five years —1890 to 1894. He pointed out that a great number of deaths under the headings of debility, inanition, convulsions, and dentition were registered as uncertified, and suggested that registrars of deaths who were medical men should try to ascertain from the informants what led up to these symptoms and to register the deaths under proper diseases. Mothers brought their infants to dispensaries suffering from the effects of improper feeding; these infants were fed on all kinds of starchy and animal food from pure ignorance. At the time of registration of birth registrars should be instructed to give to every informant a paper containing rules in relation to the proper feeding and general management of infants, &c. This document should be provided by the Government and issued to the registrars at the time they received their supply of vaccination papers from Charlemont House. Mothers who could not suckle their children throughout the early months of infancy ought to be encouraged to take necessary precautions (especially during the summer months) in feeding their infants, and it would be advisable to embody in the instructions certain directions as to how to sterilise milk.—Mr. Langford Symes said that a child might get a large amount of food but no nourishment, and a child might be starving when being fed on the richest kind of food which it was perfectly unable to digest. In children who had died from this cause it had been found that in the later stages the beautiful structures for digestion and absorption were completely abolished and the intestines were rendered like a hose or indiarubber tube, the food going in at one end and rushing out at the other.—Professor E. J. McWeeney said that, speaking from the pathological point of view, he was in great ignorance as to the exact causation of death in many cases certified as marasmus, tabes mesenterica, and the like At his own hospital it was the rarest possible thing to get a necropsy of a child under the age of five years—not one in the year. He considered that to make themselves absolutely certain as to the true cause of death an attempt should be made by the medical profession to obtain necropsies of young children by an expert in as many cases as possible. There was a danger in giving children what he might call pseudo-sterilised milk—milk Pasteurised, raised to a point below boiling point, in which lactic fermentation had been checked, but spore forming organisms were still present The lactic organisms being done away with the milk did not turn sour in the ordinary way, but the spore-forming organisms, as Flugge had shown, produced toxic peptones or albumoses which when given to animals caused diarrhœa, convulsions, and death. After Pasteurisation or sterilisation of milk it should be given to the child at once or kept at such a low temperature by being placed in cold water as to prevent growth.—The Registrar-General said that every effort in the direction indicated in Mr. Cope's valuable paper would have his most hearty coöperation. Any action must originate with the Royal College of Physicians of Ireland, and the approval of the Local Government Board of Ireland must be obtained.—Mr. A. J Horne said that, of all places, in Dublin the women took most care of their children Some of the lying-in hospitals had issued printed rules to parents, but they either threw them into the fire or if they read them they thought they knew better —Dr Ninian Falkiner presented statistics showing that in 1899, among children under one year old, the death-rate per 1000 births was 108 in Ireland and 163 in England; in 1900 the corresponding figures were 108 in Ireland and 154 in England —Mr. Edgar Flinn, Dr Herbert Byrne, the President, and others also discussed the paper.

Professor McWeeney read a paper on the Prevalence, Character, and Bacillary Richness of Tuberculous Lesions amongst Irish Dairy Cattle. His observations referred to the highest class of animal, living under ideal hygienic conditions, and kept on grass during the summer. Towards the end of lactation they were tested with tuberculin and subsequently they were sold for slaughter. A careful post-mortem examination was made and the results were controlled by the microscope, bacilli being patiently sought for in exudates and in sections of tissue. Out of 88 animals 46 were found to be tuberculous and 40 were free; two were doubtful The commonest seat of the lesions was in the posterior thoracic and bronchial lymph glands, which were more or less affected in 90 per cent. of the tuberculous animals. The lungs were attacked in 63 per cent.; the liver was much less frequently implicated, with only 8 per cent. of cases; whilst the hepatic lymph glands were attacked in 12 per cent. The alimentary canal was very rarely affected, not one case of tuberculous ulceration of the intestines being noticed and only one case of tuberculous disease of the mesenteric glands. Not a single case of tubercle of the udder was observed. The infection seemed to have been introduced through the respiratory passages in the vast majority of cases, and the relative freedom of the intestinal tract was very remarkable. Tubercle bacilli were extremely scarce, but material in which he had failed to demonstrate the bacilli microscopically had produced in guinea-pigs acute tuberculous disease with numerous tubercle bacilli.

Edinburgh Obstetrical Society.—A meeting of this society was held on May 8th, Dr. F. W. N. Haultain being in the chair.—The following specimens were shown:—Dr. J. W. Ballantyne: Two Deformed Pessaries. They were of the Albert-Smith shape and made of vulcanite; after remaining in the vagina for six weeks they became of a wide oval shape and the vaginal curve was undone. It was suggested that it was due to insufficient care in the cooling after being bent during their manufacture.—Dr. J. Haig Ferguson: Ovaries removed for Double Papillomatous Disease—Dr. Haultain: A Gravid Uterus with Fibromyoma removed by Abdominal Hysterectomy and a Thin-walled Dermoid Ovarian Tumour which had ruptured on three occasions previously to removal—Professor J. A. C. Kynoch (Dundee) read notes on Primary Carcinoma of the Female Urethra. The patient complained of slight irregular hæmorrhage and a vulvar tumour of three months' duration. There was no pain or great difficulty with micturition. Her previous health had always been good; she had passed through 12 labours. The urethral orifice was found to be dilated to the size of a sixpence; the edges were hard, ulcerated, and broke down easily on manipulation. The floor and lateral walls of the urethra were indurated from cancerous infiltration which extended nearly to, but did not involve, the neck of the bladder and internal sphincter. Other pelvic organs were healthy. Microscopically the growth consisted of atypical epithelium with abundant cell nests. With the guidance of a catheter the lower two-thirds of the urethra were excised by circular incision, and the edges of the remaining third were stitched to the edges of the portion of vestibule left. The patient remained comfortable for three months, when the occurrence of incontinence of urine for the first time showed extension of the disease backwards with involvement of the sphincter. No further treatment was consented to and the patient died 10 months later. On post-mortem examination the disease was found to be confined to the lower part of the bladder, there being no involvement of the surrounding parts. The urethra was one of the rarest organs ever affected with carcinoma. The number of published cases of affection of the female urethra did not exceed 30 and that of the male urethra only about 12 The urethra was exposed to conditions which were supposed to predispose to cancer. Fritsch suggested that the constant washing which the urethra received from the passing urine in conjunction with the consequent frequent dilatation and contraction of the canal prevented the cancer cells from obtaining that fixation necessary for growth and development. This probably accounted for the rarity with which the urethra was involved in cancer of the vulva even in an advanced stage. Unfortunately, this washing process was unable to prevent the invasion of the urethra by the gonococcus. Primary cancer of the urethra had its origin most frequently in the epithelium or glands of the mucosa where it formed either a vascular growth or a hard nodulated sessile tumour spreading along the floor of the urethra towards the neck of the bladder and eventually, by deeper extension, producing a urethro-vaginal fistula. The peri-urethral, or more correctly the vulvo-urethral, form had its origin in the epithelium at the junction of the urethral orifice and vestibule, from which it spread spirally round the urethral wall; it thus differed from ordinary vulvar cancer which spread superficially to adjacent structures, the urethra being seldom involved. Urethral cancer occurred mostly after 40 years of age; out of 27 cases four were under 40 years; three between 40 and 50 years; 10 between 50 and 60 years; nine between 60 and 70 years; and one over 70 years. Secondary cancer of the urethra, although more frequent, was not often seen. Gusserow found in 311 cases of uterine cancer that the urethra was only affected in 56 as compared with 128 of extension to the bladder The symptoms associated with urethral cancer were often slight at first, as shown in pruritus and painful micturition When the disease was advanced a tumour or incontinence of urine was complained of The treatment had not given very favourable results, out of 27 cases only two were reported free after three and six years Zweifel reported a case where the neck of the bladder was involved and excised, the parts were then sutured and a vesico abdominal fistula established by suprapubic cystotomy after the method of Witzel Goldberg reported a case where the vagina was closed by episiokleisis after establishing a recto vaginal fistula In all these cases there was recurrence within 18 months —Dr J B Buist gave an address on the Art of Vaccination Vaccination might be performed by puncture or simply by a prick, this might be done with a needle or a sharp knife, or it might be repeated over a scattered area or in close proximity to each other Another method was by incision, when superficial cuts were made in the epidermis extending to its deeper layer The lymph was inserted into the cutis because the apices of the papillary layer of the cutis were exposed Another method was by lacerations and abrasions, here the epidermis was torn through by such instruments as rakes or machines set with needles The epidermis was cut or scraped off the skin Dr Buist considered a lancet after the type of the bleeding lancet the most perfect instrument for vaccination that could be employed The area of the vesicles produced was proportional to the area of the incisions, uniform results could be obtained by incisions of the same size Dr Buist made his only one square line for each insertion and vaccinated at four points Adults should be vaccinated with the same care as infants and they should not be vaccinated more severely and not in any larger area Only a small insertion was required and if the epidermis was scratched away at this point then the vaccine vesicle would have no covering and thus be imperfect During the wide spread revaccination recently in Edinburgh Dr Buist inspected 1622 children under 14 years of age in the elementary schools Out of these 800 were vaccinated with one mark, 735 in two places, 43 in three places, and 44 in four places This showed that the usual Edinburgh method was to make one or two marks Out of these cases 351 were severe and mostly in those with one or two marks, none where four vesicles had been produced These cases were it must be remembered, second vaccinations and below 14 years, even below 10 years The severe cases showed that either the protection given in infancy was of a very evanescent character or that something might be wrong with the method of performance Experts had a gauge by which a good vaccination was calculated, if there was only one mark it should equal half a square inch, if two then each should be half that area, and so on with more But many of the cases examined were twice the approved size and must have been made by scraping off or abrading the epidermis over too large an area Lymph was an irritant and if spread over too large an area it might cause such exudation as to cause compression of the afferent vessels and necrosis from stoppage of the blood supply to the centre of the vesicle If Dr Buist used any dressing it was a powder during the second week, such as zinc powder or emol kelect A dressing of cotton wool, antiseptic or otherwise, besides interfering with the normal action of the lymph, was apt to affect the normal course of the disease as it acted as an incubation and accelerated the process Shields of all kinds were very objectionable As regards calf lymph, glycerine kept it from putrefaction but it did not keep it active, it deteriorated in a month That usually sold was composed of 20 parts lymph, 40 parts glycerine and 40 parts water The probability was that this lymph had not the same protective power, as in the recent investigation 80 per cent of the children under 14 years of age could be revaccinated and a great number of these were under 10 years of age, so that periodic revaccination had become necessary

SOCIETY OF ANÆSTHETISTS —A meeting of this society was held at 20 Hanover square, W, on April 19th, Dr J F W Silk, the President, being in the chair —Dr Dudley Buxton read a paper on the Advisability of the Inclusion of the Study of Anæsthetics as a Compulsory Subject in the Medical Curriculum [1]—In the discussion which followed Mr Walter Tyrrell said that he was doubtful as to the necessity for lectures At St Thomas's Hospital the students in rotation gave the anæsthetics under his supervision In addition a good deal of teaching was done in the special departments by his colleagues —Mr E Willett thought that it was very important that the students should attend regular lectures At St Bartholomew's Hospital, in addition to these lectures, a special class was told off every month for instruction in anæsthetics; they were mostly senior students who were not doing any other ward work In his opinion the defect of this plan was that it did not provide sufficient experience for the student and he did not think that a final practical examination was possible —Dr R J Probyn-Williams said that at the London Hospital the students were required to attend three lectures and then to receive practical instruction before they could obtain a hospital appointment He thought that systematic teaching was of great importance —Mr Harvey Hilliard raised the question whether it was desirable for the society to approach the General Medical Council on the subject —Dr Harold Low thought that there should be a recognised system of teaching, that every student should be bound to receive instruction, and that a few lectures should always be given —Dr Sampson Handley said that at Guy's Hospital there had for some years been special appointments of "clerks to the anæsthetists," and practically every man received systematic instruction in the subject —Mrs Dickinson Berry said that at the Royal Free Hospital a course of six lectures was given every term and "clerks to the anæsthetists" were appointed to hold office every month —Mr P Noble said that at the Middlesex Hospital, excepting those competing for a resident appointment, the students were not obliged to take out a course on anæsthetics —Dr G B Flux and Dr Augustus H Cook also spoke —The President said that he believed that he could claim to have introduced the systematic teaching *at present adopted* at the *Royal Free Hospital* and at Guy's Hospital to which reference had been made, and a somewhat similar system was at present in vogue at King's College Hospital With regard to Dr Buxton's suggestions there were one or two matters of detail to which he should like to refer In the first place, he considered that the teaching in nitrous oxide ought to be considered apart from the teaching in other anæsthetics, it was hardly possible to give adequate instruction in this branch of the subject in a general hospital In the second place, although he was strongly of opinion that a short course of lectures was essential, yet a considerable degree of latitude should be permitted with regard to clinical teaching *For instance*, what was *possible* in the matter of "clerks to the anæsthetists" in large schools such as St Bartholomew's, the London, and Guy's, was not always obtainable at the smaller schools, but the clinical instruction in these latter was not of necessity inferior —Dr Dudley Buxton replied —The meeting then resolved itself into the annual general meeting, and the following were elected officers for the ensuing year, viz —President Mr Walter Tyrrell Vice President Dr Dudley W Buxton Treasurer Mr George Eastes Elected Members of Council Dr Silk, Dr Probyn Williams, and Dr W D Arnison (Newcastle) Secretaries Dr Low and Dr Flux Auditors Mr Harvey Hilliard and Dr Herbert J Scharlieb

PATHOLOGICAL SOCIETY OF MANCHESTER —A meeting of this society was held on May 8th, Professor Dreschfeld, past President, being in the chair —Professor Dreschfeld described preparations from a Tumour of the Suprarenal Capsule —Dr W E Fothergill and Dr T M Scott described a case of Fibro myoma of the Round Ligament —Dr Marsden and Dr F Craven Moore showed a Preparation of Tuberculosis of the Peritoneum in a woman, aged 33 years The disease was associated with fever of a continued type, considerable adiposity, and marked bronzing of the skin The peritoneum was generally thickened over the parietes and viscera, whilst the omentum formed a solid flat tumour covering the front of the abdomen and having a few small hæmorrhages in its substance On the under surface of the diaphragm were a number of porcelain like plaques varying in size from one eighth to one third of an inch in diameter In section they showed very well the structure of the tubercle with multinuclear giant cells at the periphery —Dr Melland showed Blood films from a case of Leucocythæmia stained by different methods The best results were obtained by fixing the film with formalin vapour for three minutes, staining in 1 per cent watery solution of eosin, washing and then staining with saturated aqueous solution of methylene blue. This method clearly differentiated the nuclei, eosinophil, neutrophil, and basophil granules, and also the malarial plasmodia and nucleated red corpuscles.—Dr. A. Brown and Dr. Craven Moore described a case of Primary Carcinoma of the Gall-bladder and showed specimens. The patient, a female, aged 64 years, became ill with pain and tenderness in the region of the gall-bladder and bilious vomiting. A month later she became intensely jaundiced and she succumbed two months from the onset with symptoms of cholæmia. At the necropsy a firm mass of new growth was found involving the upper part of the gall-bladder and the adjacent liver tissue. The gall-bladder was shrunken and it contained two small cholesterin calculi. Secondary nodules of new growth were found in the liver and in the hilus involving there the hepatic ducts. Microscopically the growth was a scirrhous carcinoma originating from the mucosa of the gall-bladder.—Dr. Fothergill demonstrated Casts of the Uterus in so called Spurious Abortion and in Dysmenorrhœa.

---

[1] Reported in the Brit. Med. Jour, April 27th, 1901.

Laryngological Society of London.—A meeting of this society was held on May 3rd, Dr. Cresswell Baber, the President, being in the chair.—Dr. Barclay Baron reported on a case of Laryngeal Growth shown at a previous meeting which had now proved to be malignant.—Mr. Mark Hovell brought before the society a man, aged 61 years, from whose left vocal cord a large Epithelioma was removed by endo laryngeal operation in 1886 and again in 1887, since which there had been no recurrence. He also showed a drawing of the growth as seen in the larynx before operation and sections of the parts removed.—The case was discussed at some length by Mr. de Santi and Sir Felix Semon, to both of whom the malignancy of the growth seemed doubtful.—Dr. F. Spicer showed a female, aged 15 years, with Absorption of the Cartilaginous Septum due to pressure from nasal polypi. The loss of cartilage was thought to be due to an abscess —Dr. Lambert Lack showed a case of Unusual Laryngo-Pharyngeal Tumour in a woman, and a Microscopic Section of the Growth removed. The growth, which was attached to the mucous membrane over the cricoid cartilage, was removed by external operation. It was reported to be a mixed cell sarcoma —Dr. Lack also showed a specimen of Bony Occlusion of One Nostril —Mr. H. W. Carson showed a case of Multiple Papilloma of the Larynx —Mr. Charles Parker showed a case of Pachydermia Laryngis which had been previously shown and thought by some to be tuberculous.—Dr. Dundas Grant showed a case of Tumour of the Base of the Tongue in a young Female. The diagnosis was thought to rest between sarcoma and thyroid tumour.—Dr. A Thorne showed a case of Ulceration of the Tip of the Tongue, probably of a Malignant Nature.

Birkenhead Medical Society.—At the annual meeting of this society, held on May 10th, Dr. J. F. Blood, the President, being in the chair, the following office-bearers and members of committee for the ensuing year were elected:—President: Dr. J. Pinkerton. Vice-President: Mr. H. Laird Pearson. Treasurer: Dr. W. R. Floyd. Librarian: Mr. S Wilkinson. Secretary: Mr. J. H. Fardon. Committee: Mr. C. S. Brewer, Mr. W. Johnstone, Dr. R O. Morris, Mr. R T. Hughes, and Dr. W. Leask.

Reviews and Notices of Books.

The Medical Examination for Life Insurance and its Associated Clinical Methods, with Chapters on the Insurance of Substandard Lives and Accident Assurance By Charles Lyman Greene, M.D. St. Paul, Clinical Professor of Medicine and Physical Diagnosis in the University of Minnesota. With 99 Illustrations. London: Rebman, Limited. 1901. Pp 426 Price 17*s.*

In this work the author has endeavoured to include a description of the whole of the physical examination necessary in life assurance, together with the decisions that may be arrived at in that particular department of practice; hence, the book is a treatise on clinical diagnosis and examination for life assurance combined. At first the idea seems a good one, but in the volume now under consideration we cannot congratulate Dr. Greene on a successful production; neither part of the work is complete and both parts are greatly wanting in detail; the theoretical considerations are much better portrayed than the practical. It is assumed that many readers will be undergraduates, and, further, the author states in his preface that "within the past two years a considerable number of medical schools have introduced into their curriculum a special course of lectures dealing with the medical aspect of life assurance." That may be the case in America, but we have not heard of the plan being adopted in this country nor do we think it desirable.

The problems that come before the medical officer can only be solved by practical experience, and it is quite sufficient for the medical student to apply himself to the study of medicine and surgery without stepping aside to trifle with questions which demand considerable experience in the practice of his profession before they can be satisfactorily answered. If a practitioner is appointed as an examiner to a life assurance office it is presumed that he is acquainted with the ordinary means of physical diagnosis, and therefore we consider that Dr. Greene has not adopted a wise course in occupying the greater part of his book with matters which should be familiar to every senior student who has heard them thoroughly explained and seen them practically demonstrated by the physicians in the wards and out-patient departments. In short, the author has attempted too much. Nor are the chapters which deal solely with life assurance complete or explicit. The remarks on the Insurance of Substandard Lives suggest a great number of difficulties, but the way out of the pitfalls is only faintly indicated, and anyone fresh to the duties of medical examiner would only be more confused after reading Dr. Greene's remarks.

One of the most interesting chapters in the book is that on Attempts to Defraud Insurance Companies, in which an account is given of many cases of insurance fraud, either attempted or consummated. To the general arrangement of the book—that is to say, the manner in which reference is facilitated by means of heavy type and marginal headings—we give unstinted praise; the plan adopted is most useful and other authors might take the hint.

Materia Medica and Pharmacology. By David Culbreth, Ph.G., M.D., Professor of Botany and Materia Medica, Maryland College of Pharmacy. Second edition, enlarged and revised, with 464 illustrations. London: Rebman, Limited. 1901. 8vo, pp. 885. Price 20*s.* net.

This volume is intended more for the instruction of pharmacists and students of pharmacology than for physicians and students of the healing art. Its scope includes not only all the official medicines of the United States Pharmacopœia of to-day but also all which have at any time been official therein. There are notices, too, of allied species of organic drugs inserted with the intention of assisting students to recognise adulterations and substitutions. In addition to these are brief descriptions of the more useful of the unofficial synthetic chemical compounds. In the first edition, which was published in 1896, and which was well received everywhere, all doses were given in the United States "apothecaries" system, and degrees of temperature were expressed only in degrees of Fahrenheit. In this second edition a wise alteration has been made and all doses are given in the metric system in addition and degrees of temperature are recorded in the centigrade as well as the Fahrenheit scale. The work is valuable as a comprehensive text-book of materia medica and pharmacy, but the physiological actions of the drugs are only very briefly referred to and the medicinal uses in most cases are restricted to a mere catalogue of names of diseases. Those drugs which are poisonous have each in addition a few lines concerning antidotal measures. There is a useful chapter on the use of the microscope in materia medica. The constitution of organic carbon compounds and the methods of their chemical preparation are given very fully and their constitutions are illustrated by chemical formulæ and symbols. The illustrations are well executed. The book is well bound and well printed and is a valuable work of reference.

Histology and Pathology: A Manual for Students and Practitioners. By JOHN BENJAMIN NICHOLS, M.D., Demonstrator of Histology, Medical Department, Columbian University, Washington, D C.; and FRANK PALMER VALE, M D., Assistant in Pathology, Medical Department, University of Georgetown, Washington, D.C. Illustrated with 213 Engravings. London: Henry Kimpton. 1901. Pp. 458. Price 7*s.* 6*d.* net.

NOT only have American authors been very active in producing translations of standard German works, but during the last year or two there have been very numerous original American contributions to medical literature, some of which have been very valuable and important The book under review is one of a series—already numbering some 16 volumes—edited by Bern B. Gallaudet, M.D, demonstrator of anatomy and instructor in surgery, College of Physicians and Surgeons, Columbia University, New York. Though published as one volume, this work consists of two distinct books written by separate authors, each of whom accepts responsibility for his own part only. Normal Histology is treated in some 240 pages by Dr. Nichols, and a like space is occupied by Dr Vale with Pathology. Obviously this compression entails great conciseness and the avoidance of all discussion of doubtful points. The authors' claim for the book, indeed, is that it presents the subjects conveniently and clearly to students and practitioners of medicine, for whom the treatise is intended. On the whole, the claim is justified, though in parts, owing to the necessary brevity, the chapters read almost as a series of definitions; this is perhaps especially noticeable in the section on General Pathology, which is dismissed in some 60 pages, on many of which illustrations take up space. The arrangement of the histological portion is that generally met with.

Commencing with the cell and its development, the elementary tissues are next considered, and finally the various systems. The section on Blood and Lymph gives a good and accurate account of the present position of our knowledge, following for the most part Ehrlich's views with regard to leucocytes and recognising the degenerate character of the red cell. In the section on the Liver the glandular structure is spoken of as masked and obscure and we fear that it will remain so even after reading the chapter. The opening remarks on the respiratory system are good and considering the limits of the book a reasonable space is devoted to the central nervous system and special sense organs.

The second half of the work is divided into two portions, treating respectively of general and special pathology. A great deal of information is crowded into the space with the consequence which has already been mentioned; the various anæmias are described in some six pages. The disease and the lesions occurring are not always clearly distinguished. Thus various organisms—the bacillus of Friedländer, streptococcus, &c.—are said to produce lesions similar to those caused by the diplococcus pneumoniæ; this is perfectly true, but they do not produce the disease as defined—"an acute infectious self-limited disease with a definite clinical course."

A good deal of space is occupied by the illustrations which are taken from various sources and serve to elucidate the text, though they suffer—probably chiefly through the printing—by comparison with those found in some recently published works. The practitioner and the student, to whom the book is addressed, will certainly find in it a large amount of information, but we fancy that even these classes of readers will think the compression somewhat severe.

Qualitative Chemical Analysis, Organic and Inorganic. By F. MOLLWO PERKIN, Ph D. London: Longmans, Green, and Co 1901. Pp. 274. Price 3*s.* 6*d.*

IT is refreshing to find a new departure in the ordinary text-book of practical chemistry, and when that departure is calculated to bring facts and principles together at the same time in the students' mind we welcome the step. Dr. Perkin, like most teachers, has found amongst pupils a class who begin by reading chemistry and who prove invariably to be bunglers at the bench afterwards, and a class who carry out practical examination by following the sign-post, so to speak, of an analytical chart without any knowledge of principles. Dr. Perkin's endeavour has been to write a book in which theory and practice are more or less dovetailed. We agree with the order in which he has presented the analytical and theoretical considerations. The chapter on Reactions in Solution is excellent and brings the reader into contact with the modern theory of solution. The nomenclature suggested by Faraday for the old theory, which, curiously enough, expresses exactly so appositely the modern interpretation, is retained. Faraday called the radicles "ions," and the word "cations" is used to express the positively charged "ions" moving with the positive current, while the negatively charged "ions" moving against the positive stream are called "anions." The effect of the electric current in decomposing salts in aqueous solution is, according to modern theory, as follows. The salt is already dissociated by the water. The electric current merely neutralises the charges on the electrified radicles and thus sets them free to form new whole molecules. The radicles which are positively charged move towards a negatively charged body, while the negatively charged radicles migrate towards a positively charged conductor. The modern explanation of silver salts giving a precipitate with a soluble chloride is as follows. A solution of silver nitrate is a reagent for the detection of the anion Cl, and a solution containing the anion Cl—for example, hydrochloric acid—is a reagent for the detection of the cation Ag. But silver nitrate is clearly not a reagent for the element chlorine, for silver nitrate gives no precipitate with a solution of potassium chlorate because in solution potassium chlorate is dissociated into the cation K and the anion ClO_3. This method of teaching is a decided advance on the average text-book and is a most commendable feature of Dr. Perkin's plan. The book deals with both inorganic and organic analysis, the methods of detection and separation being identical for the most part with those described in previous practical handbooks.

LIBRARY TABLE.

The History of Ancient Gynæcology. By W. T. STEWART McKAY, M B., M.Ch London: Baillière, Tindall, and Cox. 1901. 8vo. Pp. 322. Price 7*s.* 6*d.* net.—The history of obstetrics has been fully told by Jacques de Siebold, but so far no one has attempted a similar task for gynæcology. We are so accustomed to regard the latter branch of medicine as of comparatively recent date that it is interesting to note how many are the references to diseases of women in many of the oldest medical writings. Beginning with the Papyrus Ebers, the oldest work extant on Egyptian medicine, Dr. McKay has gone through the works of the Hindu, the Greek, and the Roman writers down to the time of Paulus Ægineta. The results of his labours, carried out amidst a good many difficulties, are embodied in the present work. To enable his readers to obtain a comprehensive grasp of the subject he has given a *résumé* of the whole at the end of the book. The author shows that the ancients were familiar with the lithotomy position and employed the two methods of dilating the cervix in common use at the present time—viz., the rapid by dilators and the slow by tents. Their sponge-tents with string attached differed in no way from those of Simpson, and an instrument fulfilling all the functions of his sound was in use in the time of Hippocrates and by the Arabians. It is interesting to read, in view of the recent reintroduction of the application of superheated steam to the interior of the uterus, that in Ambroise Paré's works there is a figure with a full description of an apparatus for fumigating the womb. The book, which is of much interest, has the serious defect of possessing no index.

Diet and Food. By ALEXANDER HAIG, M.A., M.D. Oxon., F.R.C.P. Lond. Third edition. London: J. & A. Churchill. 1901. Pp. 118. Price 2*s.*—Dr. Haig's views on uric acid as a factor in the causation of disease are well known and in the present volume he teaches the doctrine of what he describes as a uric acid free diet and to that end gives recipes. These recipes mean the exclusion of all animal flesh, alcohol, tea, coffee, and similar alkaloids containing vegetable substances from the diet, rigidly excluding, as he says, "the poisons which cause friction and jar in the machinery." We fear the following daily regimen would not appeal to many people. Breakfast, one pint of milk with a plate of potatoes, bananas, pears, apples, plums, or other fresh fruit. Lunch, vegetable soup made with milk, plate of potatoes, two ounces of cheese eaten with potatoes and other vegetables in season, stewed fruit or tart, fresh fruit; one pint of milk drunk during the meal. Dinner, much as lunch, one pint of milk, half an ounce of cheese. This is all very interesting theoretically and no doubt chemistry and physiology teach that this diet would be sufficient for the maintenance of the human organism, but how sadly the palate would suffer, and the palate may surely be reckoned as a dietetic factor. What Dr. Haig classes as the diets which are uric acid free have been employed as food for generations without affecting the duration of life appreciably. Intemperance is, of course, responsible for autotoxic processes, but then the intemperance of temperance is the other extreme which would cut out of life many innocent joys.

Dental Metallurgy: a Manual for the Use of Dental Students and Practitioners. By CHARLES J. ESSIG, M.D., D.D.S., revised by AUGUSTUS KOENIG, B.S., M.D. Fourth edition, revised and enlarged. London: Henry Kimpton. 1901. Pp. 286. Price 7*s.* 6*d.*—Metallurgy is, of course, an essential subject in the dental student's curriculum, and the issue of a separate work devoted to the chemistry and physics of the metals is a need supplied. Though the properties of the metals are described in chemical text-books, yet they are not described with any particular bearing on dentistry. The book before us, therefore, will be welcomed by dental students, inasmuch as it presents just those facts about the metals and their compounds which concerns his particular vocation. The authors are teachers of the subject in the University of Pennsylvania and their experience of the needs of dental students is valuable. The chapter on Amalgams will be particularly useful, while the method of analysis of alloys will help the student to ascertain their composition. Following upon the description of mechanical methods the metals used in dentistry are individually dealt with. Dentistry, like other branches of professional work, is advancing rapidly and the student and dental practitioner must keep pace with these advances They will find that a perusal of this book will place them *au courant.* We note that the authors give references more than once to Percey's metallurgy. We presume they refer to Dr. Percy's well-known work.

The Mind of the Century. London: T. Fisher Unwin. 1901. Pp. 142. Price 2*s.*—This is a reprint of a series of articles which appeared in the columns of the *Daily Chronicle* towards the close of the last century. The sketches are necessarily brief and imperfect and the title is presumptuous. The series of essays gives but a scant notion of the mind of the century. It could not be otherwise when "Applied Science" is dismissed in nine pages, "Natural Science" in not quite nine pages, "Medicine" in nine pages, and so on. In the section on Applied Science the author touches merely the fringe of the great subjects involved, and he even omits any mention at all of the influence on industrial processes of chemical discoveries. The book would better be described as a conspectus of the progress of the past century.

JOURNALS AND MAGAZINES.

Birmingham Medical Review.—In the opening article of the May number Mr. George Heaton discusses the surgery of the stomach in much detail, describing operations for perforated ulcer, subdiaphragmatic abscess, gastro-jejunostomy, and the treatment of cancer of the stomach. Sir James Sawyer recommends unguentum ranunculi ficariæ in the treatment of conditions of a hæmorrhoidal character affecting the anal margins. The ranunculus ficaria, popularly known by the names of lesser celandine and pile-wort, is a well-known British wild perennial plant. The plants, gathered when they are blooming in the spring, are cut into small fragments and kept immersed in melted pure hog's lard at a temperature of about 100° F. in the proportion of one part by weight of the plant to three parts of lard for 24 hours. At the end of that time the portions of infused herb in the melted lard are subjected to sufficient pressure to produce the yielding of their juices to the fatty infusion, which infusion is thereupon strained and allowed to solidify. The ointment should be bright olive-green. Care should be taken not to raise the temperature of the mixture too high lest the colour be spoiled. Dr. E. A. Sadler records a case in which 20 grains of sulphonal produced drowsiness on the afternoon of the day after that on which it was taken, and on the following day—i.e., the second after taking the drug —pyrexia and semi-coma.

Quarterly Medical Journal.—In the May number Dr. James Kerr of Bradford records 18 cases of Tobacco Amblyopia and gives an analysis of 51 additional cases. Dr. George Lorimer of Buxton writes on Gout in connexion with Lead Impregnation. Mr. R. J. Pye-Smith describes a Reproduction of the Tibia after Removal of the Diaphysis for Acute Infectious Periostitis and Osteomyelitis. The formation of new bone is shown in a skiagram.

Grèce Médicale.—In the April number Dr. Triantaphyllides of Batoum records a case of Uncontrollable Vomiting Treated by Suggestion. The patient was 30 years of age and in the first month of her seventh pregnancy. Unsuccessful attempts to induce premature labour had been made. Dr. Triantaphyllides on taking charge of the case assured her that abortion had taken place and that the uterus was empty. He stopped all local treatment and gave bread pills every three hours. The vomiting soon ceased almost entirely. Labour followed at term. Dr. M. Mangakis of Athens mentions a case in which a girl, aged 18 years, twice presented symptoms of vicarious menstruation from the right ear and nostril.

Analytical Records

FROM

THE LANCET LABORATORY.

---

(1) GERM-FREE INVALID MILK; AND (2) GERM-FREE MOTHERISED MILK (CRYSTAL BROOK BRAND).

(J. Carson, Crystal Brook Farm, Theydon Bois, Essex.)

THESE specimens are the products of a milk farm kept under strict scientific and sanitary control. In addition the milk is obtained from prize Jersey cows which are periodically examined, each having successively withstood the tuberculin test. The farm, which we have visited, is situated at Theydon Bois in Essex amongst excellent pastureland and in a very healthy environment. Extraordinary pains are taken to produce a healthy milk and a milk of excellent quality. Our analysis of the invalid milk was as follows: total solids, 14 10 per cent.; fat, 5 per cent.; non-fats, 9 1 per cent.; and mineral matter, 0 72 per cent. The richness in cream is a remarkable feature of the sample. The "motherised" milk gave the following results of analysis: total solids, 12 02 per cent.; consisting of milk sugar, 6 32 per cent.; fat, 3·37 per cent.; casein, 1·79 per cent.; and mineral matter, 0 54 per cent. This composition accords with genuine mother's milk except in regard to the mineral matter which cannot be avoided owing to the higher percentage of salts in cow's milk. The process of "motherisation" and sterilisation are efficiently conducted and, what is of the greatest importance, these steps are begun directly after milking, the risk of contamination being thus reduced to a minimum. Prior to these processes the milk is filtered. As might be expected the milk is excellent in all respects, one satisfactory feature being that *even after several days* it keeps perfectly sweet after the stopper has been removed. This is excellent evidence in favour of the *freedom* of the milk from all organised impurities. We observed on the occasion of our visit to the farm that the dairies *are separate from* any part of the farm buildings or cow-houses. Such a farm is an excellent example of milk-farming, being conducted on correctly hygienic lines, producing not only milk of a high quality but milk entirely free *from* any disease-producing impurities. In view of these results it is not surprising to learn that the milk has proved highly *satisfactory* in the feeding of infants and invalids.

FRUIT CHUTNEY.

(T. H. Kesterton, 200, Strand, London, W.C.)

This chutney contains an assortment of fruits and is manufactured on a farm in Sussex It is not very much like Indian chutney and, in our *opinion*, not so good. Its flavour is very mild and lacks piquancy. It is evidently made *from* good materials and we could find *no objectionable* antiseptics present or any sign of metallic contamination. Doubtless this mild form of chutney may suit many tastes, but in our opinion it requires more zest as a sauce or condiment; however, *this is* an improvement which could easily be made.

TABLOIDS: (1) BETA-NAPHTHOL COMPOUND; (2) IRON CITRATE COMPOUND; AND (3) CODEINE AND NUX VOMICA.

(Burroughs, Wellcome and Co., Snow Hill-buildings, London, E.C.)

Beta-naphthol is well known as an anti-fermentative in dyspepsia and its association with wood charcoal and peppermint should be valuable in digestive disturbances. The compound beta naphthol tabloid contains one grain of beta-naphthol, four grains of wood charcoal, and half a minim of oil of peppermint. The tabloid iron citrate compound presents a well-known formula in a convenient form, whilst the purity of the ingredients is guaranteed. The tabloid is sugar-coated and each contains *three grains of citrate of iron* and ammonia, one grain of sulphate of quinine, and one-sixtieth of a grain of arsenious acid. Lastly, the tabloid codeine and nux vomica contains one grain of phosphate of codeine and a quarter of a grain of extract of nux vomica. The formula is designed for diabetic patients with a view to diminishing the excretion of sugar—a property of codeine.

(1) SOLUTION ADRENALIN CHLORIDE; AND (2) SUPRARENAL LIQUID WITH CHLORETONE.

(Parke, Davis, and Co., 111, Queen Victoria-street, London, E.C.)

Adrenalin is described as being the active *principle of* the suprarenal gland separated by a chemical process. Adrenalin occurs in tiny fusiform crystals which apparently dissolve easily in hydrochloric acid producing a definite chloride. The solution is a cardiac and vaso-motor stimulant, astringent, and hæmostatic. The solution contains one part of the chloride dissolved in a thousand parts of normal sodium chloride solution. It is said to be employed successfully for performing bloodless operations, and so powerful is the suprarenal principle that a single drop *of a solution of the strength* of 1 in 10,000 instilled into the eye blanches, it is stated, the conjunctiva, ocular and palpebral, in from 30 *seconds to one* minute. We have already described the local anæsthetic and antiseptic properties of chloretone in THE LANCET of Jan. 13th, 1900, p. 106. Those properties are taken advantage of in the preparation of a suprarenal liquid to which chloretone is added, the result being a preparation combining the local anæsthetic and antiseptic properties of chloretone with the extraordinary styptic qualities of the suprarenal extract.

EXTRAIT DE MALT (BIÈRE DE SANTÉ).

(Agency: W. P. Goodale, 64, Leadenhall-street, London, E.C.)

This is a somewhat syrupy fluid with strong malt flavour resembling that of lager beer. Apparently it is derived by concentrating lager beer by evaporation. It is only slightly alcoholic, as will be seen from the following results of analysis which we obtained: absolute alcohol, by weight 2·06 per cent., by volume 2·58 per cent., equal to proof *spirit 4·52* per cent.; and malt extractives, 20 37 per cent. The liquor is undoubtedly nutritious, but somewhat mawkish to the taste. According *to our experiments it* is without digestive action upon starch, the diastase probably having been destroyed by heat during concentration. *It contains* all the extractives of malt, including the sugars, dextrine, *nitrogenous* principles, and salts. On this account it is, *of* course, a food of some value, but we fail to see its advantage over a good *preparation of malt* extract, especially as it exhibits no diastasic properties.

(1) CODEINE NEUTRAL TARTRATE; AND (2) APOMORPHINE HYPOPHOSPHITE.

(J. F. Macfarlan and Co., Abbeyhill Chemical Works, Edinburgh, and London.)

The specimens sent to us offer *important* advantages for hypodermic purposes, first because they are more *soluble* in water than the ordinary salts, and secondly because *they* are not acid but neutral. The codeine neutral tartrate *is more* soluble than the acid phosphate of codeine, the *solubility* being about one part in two parts of water, and the dose is from a quarter of a grain to two grains. The hypophosphite of apomorphine is soluble in about six parts of water, whereas the hydrochloride is only sparingly soluble, one part *dissolving in 50* parts of water. The hypodermic dose of *apomorphine hypophosphite* is from one-sixteenth to one-sixth of a grain.

THE LANCET.

LONDON: SATURDAY, MAY 25, 1901.

The Approaching Meeting of the General Medical Council.

WE are probably safe in assuming that the next meeting of the General Medical Council is anticipated with exceptional interest. The Executive Committee meets on June 3rd, the day preceding that on which the General Medical Council meets. It has as one of its chief duties the arrangement of the business of the Council for the first day of the session. It will do a great service if it can contrive to secure that the early days of the meeting shall be used for the discussion of the really important questions which demand the attention of the Council, and can prevent the waste of time which has contributed so largely in producing the present unsatisfactory position of the Council's finances. There are topics which present themselves for consideration session after session and year after year. These hardy annuals should be disposed of on some principle and with some firmness or they will bring the Council into discredit. The following subjects will call for attention from the Council. The financial position of the General Medical Council and of the branch councils will be considered in the light of the special report from the expert selected by the treasurers in accordance with the resolution of the Council at its meeting last December; the modest amendment of the Medical Acts practically agreed on, as between the medical authorities and the General Medical Council on the one hand and the Privy Council on the other; the recognition of foreign or colonial diplomas, a subject which has been brought before the Council by a communication to the Colonial Office asking for the recognition of the medical degree of the University of Malta; the examinations of the Apothecaries' Hall of Dublin, the special inspection of which has been a costly charge on the Council for the last few years; the list of exemptions granted by the medical authorities in any part of their examinations held in 1897, 1898, and 1899; and the disciplinary cases referred from last session, with any cases that may have arisen in the interval, to be reported on by the Penal Cases Committee. This does not pretend to be an exhaustive list of the subjects which must find a place in the programme of the Council—indeed, we have omitted one of the most important—but it is sufficiently long to show the need for a methodical routine of procedure on the part of the executive and business committees which are largely responsible for the order of business.

It is, in our opinion, impossible not to see that the financial position of the Council calls for serious consideration. There may be nothing alarming in the financial position of the Council, but it is obvious to all, on the showing of the Finance Committee, that the expenditure of the Council is increasing, while its reliable income remains practically stationary. The General Medical Council has very little income. Its main wealth consists in its power to demand from the branches the sum needed to pay its expenses. The growth of this demand is the serious element in the financial statement. Making allowance for the fact that the General Medical Council holds a good property in its offices and house in Hanover-square, though for the present heavily mortgaged, it is impossible to view without concern the growing expenditure of the Council or to doubt that some means ought to be devised for lessening it if the English and Scottish branches are not to be impoverished as the Irish branch has already been. It is not enough to say that this state of matters arises from the addition of seven members to the Council since 1858 and the introduction of topics for discussion which seldom arose in the early days of the Council. The Council cannot afford to be out of sympathy with the profession which supplies its funds. It may exist primarily for the protection of the public, but it has charge of the professional status of the medical man and must turn a willing ear to all matters concerning the maintenance of that status. It cannot decline to discuss questions which affect the *morale* of the profession without abandoning one of its statutory functions. But it must find some way of doing its work and keeping its expenditure within its income. Theoretically this would best be secured by abolishing the individual representation of the licensing bodies and so moderating the size of the Council, but this implies legislation that would be stoutly resisted by each and all of the medical institutions, and we have to look elsewhere for a feasible remedy. Meantime all members of the Council can add to its credit and their own by discouraging loose and unpractical work. The fees of the Council constitute its chief expenditure—and we hasten to say that it would be a quixotically foolish economy for the Council to do its work without being paid for its labours. But it would stamp them as worthy of the trust reposed on them if they would confine their words to the most modest dimensions, debate questions of practical importance only, and arrive as quickly as possible at definite courses of procedure. The Council cannot afford to disregard questions of professional conduct which have arisen in new forms of late years. But it should carefully and quickly ascertain what are the limits of its own duty and power and then firmly resolve to keep within them. Otherwise expenditure will continue to grow in a greater ratio than income.

There remains for notice one subject that is sure to engage the attention of the Council very seriously, that is the position taken up towards it by the Royal College of Physicians of London and the Royal College of Surgeons of England in respect of the teaching of the preliminary sciences. We must express a hope in regard to this dispute that both parties will come to the Council with a disposition to find some way of ending it. The General Medical Council has not always been happy in its relations with the licensing bodies, and it really seems to have no jurisdiction over the Colleges in this matter. On the other hand, the teaching of the preliminary sciences is fundamental and affects the whole course and efficiency of the medical curriculum, and the Privy Council may think the General Medical Council right in trying by its regulations to influence the curriculum required by the Colleges. One thing is clear, that the dispute should be settled amicably between the Council and the Colleges. It is bad for the medical profession that difference of opinion between the Council and the Colleges should be pushed so far as to necessitate reference to the Privy Council, while recourse to law would be simply deplorable in the loss of prestige to one party or the other that would be entailed.

◆

The Re-organisation of the Army Medical Service.

SIR JOHN BATTY TUKE put a question to the Secretary for War in the House of Commons on May 17th as to whether it was proposed to adopt the suggestion, contained in the report of the Royal Commission on the South African Hospitals, that a departmental or other committee of experts should be appointed to decide upon the steps needed to effect certain reforms in the Royal Army Medical Corps, and, if so, whether he was prepared to state the composition of such committee? Lord STANLEY, Financial Secretary to the War Office, said, in reply, that the Secretary of State was preparing various proposals to submit to a committee of experts, but that the composition of the committee could not at present be stated. That the subject is one of national importance we need not point out; nevertheless, we do not regret any delay that may be necessary in order to have a full, free, and independent inquiry started. Much will, of course, depend upon the selection of a president and the composition of the committee. It goes without saying that the Army Medical Service will be represented. For in any attempt to adjust the medical requirements and provisions to the needs of the Empire and modern war it is only those who are practically, as well as theoretically, acquainted with the existing systems of military organisation and administration who can be in a position to furnish the committee with reliable information, and it will require men of military training to appreciate their evidence. But so that this aspect of the question is duly represented we see no reason why the military, or military medical, element should be the predominating one. There is no objection to the civil element being largely represented. What is required is that the committee should comprise men of independence of character and business capacity.

With a committee so constituted we may be sure that no schemes or proposals which did not commend themselves to educated men of ability and common sense would be entertained. The inquiry should be of a sufficiently deliberate character to enable the committee to arrive at some definite conclusions and recommendations on which a scheme of army medical reform may be formulated by the Government, so sound and well-balanced that it has a good chance of being accepted as reasonable and just by the public and the medical profession, civil and military alike. The problem is confessedly a difficult one. If the committee can succeed in solving it they will render a great public service. They will certainly likewise earn the gratitude of the medical profession, which is tired of seeing the Army Medical Service so frequently aspersed and identified with failure, notwithstanding that the individual medical officers composing it are at the same time extolled for zeal, devotion, and bravery displayed in their war duties. In the meantime it is officially announced that various proposals are being prepared by the War Office for submission to the forthcoming committee, who will be furnished from the beginning with plenty of food for reflection. An enormous amount of evidence that reform is needed, and an equally large amount of suggestions—of varying value, by the way, and not always emanating from responsible persons—with regard to the directions that reform should take have appeared in the public press, while the British Medical Association have recently contributed most interesting material for consideration in the shape of a provisional report on the Army Medical Service. This report, which contains detailed recommendations for the re-organisation of the service, has been drawn up by a sub-committee of the Parliamentary Bills Committee of the Association, and, having been adopted by the Council of the Association, was published as a supplement to the *British Medical Journal* of May 4th last. The report has a wide scope and is of an elaborate and exhaustive description. It has evidently been industriously and carefully drawn up and contains a good deal of useful and pertinent information. If some of this is not exactly new to the medical profession, it will all bear repeating, and the grievances of the Army Medical Service are of long standing. We do not know whether the sub-committee's inquiries were addressed to all the universities, colleges, and medical schools in the United Kingdom, but replies have been received from 33 of them, of which a list is given and the results are thrown into tabular form. The sub-committee proceed to group, analyse, and summarise these replies under certain general and specific heads and are thus able to formulate a series of proposals for the re-organisation of the service, which have received the imprimatur of a number of representative bodies.

Adverting to the series of articles which have recently appeared in THE LANCET in connexion with the report of the Royal Commission on South African Hospitals we hope that, among other things, one point will not be lost sight of either by our readers or by the promised committee of experts. We are entirely in favour of remedying what we have always regarded and characterised as a grave defect in the Army Medical Service. Nothing is held out as a reward for professional or scientific attainments, and so little is done in the way of the selection of medical officers for promotion to the higher posts of the service for their merits, instead of as a mere matter of seniority, that it might be imagined that no regulations had ever existed especially providing for selection where it is deemed proper. That a process of selection should be properly put into action forms one of the principal points in the scheme of re-organisation set forth in these columns. After dwelling upon the importance of giving medical officers every practicable facility for professional study and saying that the Director-General should have such a record of the capacities, qualifications, and characters of his officers as to enable him at any moment to put his finger on the right men to fill the right places, we pointed out that promotion by selection had practically been neglected or fallen into abeyance, and added that "there should, in our opinion, be far more rewards held out for professional merit." To make the Army Medical Service a pure seniority service is, in our opinion, tantamount to passing a sentence of death upon it. Up to a certain rank, and in order to deal fairly and justly with officers of average ability and attainments with an average amount and quality of service, seniority should be the rule; but for all above that rank selection should be the rule. Medical officers who have rendered exceptional service (professional, scientific, or otherwise) or who are in possession of high qualifications should, if they are to be rewarded by promotion, have their names placed upon a separate list, or the step in rank should be of the nature of brevet rank, otherwise their reward will be obtained at the cost of their brother officers over whose heads they will pass and not at the expense of the State, as should be the case. We need scarcely say that other things are required besides high professional or scientific attainments to qualify a man to make a good administrative officer. We are fully alive also to the fact that promotion by merit may be worked to mean, as it is so often alleged to mean, interest or something other than merit, and we would consequently have the grounds of selection set forth and recorded and the record kept at the headquarters of the Army Medical Service, open to the inspection of all whom it might concern. Jobbery, and even the suspicion of jobbery, must be avoided.

The Festival Dinner of the Polyclinic.

THE festival dinner of the Medical Graduates' College and Polyclinic was held at the Hotel Cecil on May 22nd. The Leader of the House of Commons presided and was supported by men eminent in many departments of human endeavour, politicians, social celebrities, Church dignitaries, peers, and distinguished representatives of the colonies. The occasion was noteworthy in several ways, for the institution whose promoters have received an unmistakeable token of encouragement is novel in this country, while the public have never before been so frankly taken behind the scenes of medical education and been shown its difficulties, its limitations, and its great aspirations. All of us looking back on our student days will remember the time when everything was strange and new, when the intricacies of anatomy, chemistry, and physiology taxed our memories, and the unwelcome prospect of examinations in due course engrossed our thoughts. With the students of the Medical Graduates' College this is not so. They have mastered the essentials of their profession and their only object now is to increase the stock of experience which they have gained, to systematise their knowledge, and to train themselves in the art of turning it to practical account

The need of such an institution is a very real one, for medical science has become so extensive and has developed itself in so many different directions that the well-equipped practitioner requires to know at least something of almost every department of physics and biology, and must do what he can to seize the leading points of an enormous technical literature. Those who do not hold any hospital appointment and are absorbed in the multitudinous cares of professional life may well be excused if they fail to realise these ideals, but the inevitable penalty is that if there is no progress there must be retrogression, so that as the years advance a period of "rustiness" must arrive and the veteran find himself at a disadvantage as compared with those who are destined to be his successors. Post-graduate study, participation in the work of medical societies, and judicious reading are the most available antidotes. The young man, who has satisfied the examiners and received his diploma, soon discovers that the conditions which he encounters in private practice are not just the same as those with which he was familiar in the hospital. For one thing, the hospital patients are themselves to a certain extent a selected class—either actually suffering from some of the worst ills to which flesh is heir, or at least presenting symptoms of impending trouble which, when analysed by a skilful teacher, may form the groundwork of an interesting study. In private practice, however, the clinical material is less concentrated, so to speak; minor ailments prevail, and surgical cases are less common than might be expected; but the practitioner must never forget that a good store of sound clinical knowledge is of the first importance to him. The art of reading symptoms aright and the ability to forecast the probable course of an illness or the consequences of an injury must be diligently cultivated. And for the encouragement of the faculties of observation and the acquisition of new ideas invaluable opportunities are afforded at the Medical Graduates' College. Post-graduate study, whether called by that name or not, must of necessity always exist in some form or other, for medicine and surgery are inherently progressive, fresh discoveries are every now and then superseding currently accepted views, and new methods of diagnosis are constantly being introduced. Without going so far back as the pre-anæsthetic days, who of us that has passed middle age does not remember the time when the clinical thermometer was an unfamiliar object, when the microscope was scarcely applied at all in clinical work but only in the anatomy class-room, when the recognition of anæmia by examining the blood was only beginning to be talked about? At that time the rapid and secure identification of tuberculosis, diphtheria, and malaria by means of their microbes was unthought of, and no such prompt diagnosis of plague as is now a matter of daily routine was possible. These aids to the practitioner in his struggle with disease depend on the employment of instruments of precision and the utilitarian application of laboratory methods, the latest acquisition in this field being the Roentgen rays, by the help of which many obscure surgical problems are promptly solved. Surgery itself has been revolutionised in every department by Lord LISTER, whose discoveries were given to the world about 35 years ago, and during the same period the modern methods of dealing with epidemic disease other than small-pox have been evolved by the labours of many sanitarians. On the notorious success of the sanitarians we need not dwell.

But developments of medicine as they occur require to be brought to the notice of the medical profession as a whole if the public is to obtain full benefit from them. The professors and teachers of the great medical schools and their students enjoy opportunities which the Polyclinic aims at affording to all medical men For which reason we think the Polyclinic deserves to obtain the considerable measure of public support which Mr BALFOUR in an eloquent speech, reported elsewhere in our columns, demands for it Mr BALFOUR'S suggestion that we as a nation have of late fallen behind Germany, France and Italy in the ardour of our pursuit of knowledge should give all thoughtful people a subject for reflection Do we lack the imagination required to show what apparently remote and abstract studies do for the service of mankind? asks the most philosophic of our statesmen And he evidently expects a positive answer The spirit of research, of ardent uncompromising intent to get at the truth of things, stimulates the work of British medicine as vigorously now as in the past and as conspicuously here as it does in any other country But we are not certain that our lay fellow-citizens can clear themselves from the reproach of being apathetic to the developments of medical science The Englishman, proud of being practical, likes to pay for results, and in medicine tangible results cannot always follow honest work We hope that Mr BALFOUR'S words may help the public to take a large view of medical science, and may influence them to see, and persuade them to support, honestly directed medical research It will be seen on reference to his speech that Mr BALFOUR grounded his appeal for funds upon three separate heads, and that we have only referred to his arguments for the endowment of research This is because we feel that the scope of the Polyclinic's work must be more defined, and its position towards the public and the medical practitioner as a charitable institution made more exactly clear, before it can expect the unanimous support of the medical profession

Annotations.

"Ne quid nimis."

THE ANNUAL REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD

THE annual report of the medical officer of the Local Government Board for the year 1899-1900, in supplement to the Board's annual report, has made its appearance and relates almost wholly to the proceedings of the medical department in the latter months of the late Sir Richard Thorne's tenure of office Among the appendices will be found, as in previous years, some extremely interesting articles Many of these have been reviewed in our columns as reports of assistant medical officers of the Board to the principal medical officer, and taken as a whole they constitute a summary of the public health administration of the country which is of the utmost value An article of great interest is that supplied by Dr R Bruce Low upon the progress and diffusion of the plague in 1899 1900 This is in addition to a short account given in Sir Richard Thorne's last annual report showing the progress and diffusion of plague throughout the world from 1879 to 1898 as far as records of the manifestation of the disease could be obtained This valuable contribution is followed by a memorandum by Dr Bruce Low upon the precautionary measures taken in 1899 to prevent the importation of bubonic plague into England and Wales The marked success which has attended the sanitary measures of Great Britain and Ireland in excluding plague from this country, although we remain in touch through our widespread commerce and far reaching possessions with a dozen infected centres, redounds to the credit of the Local Government Board We think that every medical man would do well to read these papers and see how the good results have been obtained We shall as usual deal with the report in a short series of articles

THE INDIGESTION OF LONELINESS

AT a time like the present, when the marrying age of the average man of the middle classes is being more and more postponed, the physical ills of bachelordom come increasingly under the notice of the medical man It is not good for man or woman to live alone Indeed, it has been well said that for solitude to be successful a man must be either angel or devil This refers, perhaps, mainly to the moral aspects of isolation, and with these we have now no concern There are certain physical ills, however, which are not the least among the disadvantages of loneliness Of these there is many a clerk in London, many a young barrister, rising, perhaps, but not yet far enough risen, many a business man or journalist who will say that one of the most trying features of his unmarried life is to have to eat alone And a premature dyspepsia is the only thing that ever takes him to his medical man There are some few happily disposed individuals who can dine alone and not eat too fast, nor too much nor too little With the majority it is different The average man puts his novel or his paper before him and thinks that he will lengthen out the meal with due deliberation by reading a little with, and more between, the courses He will just employ his mind enough to help, and too little to interfere with, digestion In fact, he will provide that gentle mental accompaniment which with happier people conversation gives to a meal This is your solitary's excellent idea In reality he becomes engrossed in what he is reading till suddenly finding his chop cold he demolishes it in a few mouthfuls; or else he finds that he is hungry and paying no attention to the book, which he flings aside, he rushes through his food as fast as possible, to plunge into his armchair and literature afterwards In either case the lonely man must digest at a disadvantage For due and easy nutrition food should be slowly taken and the mind should not be intensely exercised during the process Everyone knows that violent bodily exercise is bad just after a meal, and mental exertion is equally so Wise people do not even argue during or just after dinner and observation of after dinner speeches will convince anyone that most speakers neither endure themselves nor excite in their hearers any severe intellectual effort In fact, the experience of countless generations, from the Red Indian of the woods to the white shirted diners of a modern party, has perpetuated the lesson that a man should not eat alone, nor think much at this time, but should talk and be talked to while he feeds Most people do not think much when they talk, and talking is a natural accompaniment of eating and drinking How does it fare with the many solitary women of to day? No better, we know, than with the men, but differently Alone or not a man may generally be trusted at any rate to take food enough (We suppose, of course, that he can get it) With a woman it is different She is more emotional, more imaginative, and less inclined to realise the gross necessities of existence Therefore the woman doomed to dine alone as often as not does not dine at all She gets dyspepsia because her digestion has not sufficient practice; a man gets it because his functions practise it too often in the wrong way. Worst of all, perhaps, is the case of the solitary cook. In the myriads of small flats in London there are thousands of women "doing" for their solitary masters or mistresses. These women, whose main occupation is to prepare food for others, find it impossible to enjoy, or even to take, food themselves. As confectioners are said to give their apprentices a free run of the stock of the shop for the first few days, knowing that it will effectually cure appetite afterwards, so the women who are always occupied with buying and preparing food grow unable to use it for themselves These people suffer from dyspepsia, which is cured if somebody else manages their kitchen for a week, allowing them to take meals without preparing them. It needs no moralist to declare the evils of solitariness. Man and woman is a gregarious animal. Physically and intellectually we improve with companionship. Certainly it is not good to eat and to drink alone. It is a sad fact of our big cities that they hold hundreds of men and women who in the day are too busy and at night too lonely to feed with profit, much less with any pleasure.

THE MEDICAL ASPECTS OF CANCER OF THE BREAST.

In the first two numbers of *American Medicine* Professor Osler has published a useful article on the above subject. In cancer of the breast metastasis in the bones and other parts may occur at any period, early or late. Mr. T. W. Nunn has described the case of a woman, aged 27 years, who had in April cancer of the left breast which she had noticed for several months. There was left ptosis in June; subsequently paraplegia occurred. On the other hand, Professor Osler observed metastasis as late as 18 years after the discovery of the breast tumour. He divides the secondary manifestations into cerebro spinal, thoracic, and abdominal. The skull and brain are not often affected. The spinal group is, perhaps, the most important Billroth remarks that cancer of the spine is seen particularly in the atrophic form of scirrhus. From a diagnostic standpoint this fact is of great importance, for the patient may overlook the primary growth and come under treatment for the spinal symptoms which may be misunderstood by the unwary. The pains may be regarded as rheumatic, neuralgic, or hysterical. Charcot insists that in any case of painful paraplegia, particularly if the patient is a woman, atrophic indolent scirrhus of the breast should be looked for. Referring to one case he says: "Struck by special characters presented by the pain and calling to mind some of the facts which I had observed at the Salpêtrière, I asked if there was not a lesion of the breast. The reply was negative, but, to the great astonishment of the patient, I found one of the breasts retracted with an atrophic scirrhus." Professor Osler describes a similar case: a woman, aged 52 years, had been complaining for five or six months of severe pains in the neck which were thought to be neuralgic and rheumatic. She looked well and was fairly nourished, though she had lost considerable weight. As she rested in bed she had no pain, but when she attempted to move the head she felt pain in the back of the neck. She walked well, but carried the head stiffly. The knee-jerks were increased. Scirrhus of the left breast was found which at once threw light on the case. Cruveilhier described spinal cancer and gave the condition the name of "paraplegia dolorosa." Charcot has given a very clear account of it in one of his lectures. The main features are intense pains in the sides and down the legs, or, if the secondary growths are higher, in the arms. There are areas of anæsthesia; sometimes there is the so-called anæsthesia dolorosa, and herpes zoster may break out. One feature of the pain is characteristic: the patient may remain in a comfortable position for an hour or more, then the slightest movement of the spine produces torment. There may be extreme symptoms of pressure on the nerve roots without paraplegia. When pressure on the cord begins there are often painful spasms in which the legs are drawn up. Ultimately there may be complete paraplegia. A remarkable fact is that the spinal symptoms may disappear and the patient recover from a desperate condition of "paraplegia dolorosa" sufficient to be able to walk about. Professor Osler describes the case of a woman, aged 30 years, who began to have pains in the back and chest in August, 1899, 18 months after removal of the left breast for cancer. Shingles over the left side and shoulder appeared. She had a winter of great suffering. In March, 1900, she complained of difficulty in walking. Complete paraplegia, sensory and motor, followed. In July she began to improve. The paraplegia gradually disappeared and though stiff she could walk with a cane. Professor Osler gives no explanation of this curious recovery. Probably it was due to absorption of the secondary growth—an event which occasionally occurs in malignant disease.

DYING DECLARATIONS.

A medical practitioner was arraigned at the recent sessions of the Central Criminal Court upon a charge of murder of a woman, and was also indicted for using an instrument upon her with intent to procure her miscarriage. The case did not proceed far because the principal evidence tendered by the prosecution consisted in a dying declaration made by the deceased woman. The circumstances in which the declaration was made were proved, and Mr. Justice Bruce ruled it to be inadmissible as evidence. The declaration had not been made in the settled hopeless expectation of immediate or almost immediate death, which condition the law imposes in its anxiety that the prisoner in such serious cases may not be judged upon anything that may possibly have been said in malice and untruly. The dying declaration, which is used, when properly made, in cases where the death of the deceased forms the subject of the inquiry, must not be confused with the "deposition" of a sick or deceased person which may be read at the trial of any accused person, if it was taken in his presence before a magistrate and with opportunity afforded to him of cross-examining or protesting. In the case in question the declaration was further inadmissible because it was made in answer to questions and not as a voluntary unprompted statement and because a record had been made of the replies but not of the questions asked. We note these points because declarations of this kind are frequently made at the suggestion of the medical practitioner when he sees that there is no hope of his patient's recovery and when he suspects that there has been foul play. A declaration thus made is not more admissible because it was taken before a magistrate, although no doubt the presence of a justice of the peace may add authenticity and weight; the deposition, on the other hand, is taken with proper formalities by a magistrate. We observe that in the particular case there would have been a direct conflict of medical evidence as to the cause of death, had the trial proceeded, and that the accused had consistently denied that he did anything to procure a miscarriage. It may have struck some as strange that with this conflict of evidence the grand jury should have returned a true bill. It must be remembered, however, with regard to this that just as it is the duty of the magistrate to commit for trial so it is the duty of the grand jury to bring in a bill where they are satisfied that there is a *primâ facie* case against the prisoner. The admissibility of the dying declaration was for the judge and he only decided the point after the bill was found, while it was not at all necessary that all the evidence for the prosecution, some of it inconsistent perhaps with other portions, should have been before the grand jury at all That body, as soon as it is satisfied that there is a *primâ facie* case on evidence that has been laid before it, may find a bill without waiting to listen to any more

THE BRAINS OF TWO DISTINGUISHED PHYSICIANS.

THE study of the brains of distinguished men is always fraught with interest because of the possibility of correlating exceptional endowments with special conditions of cerebral organisation and development Up to the present day but few brains of really eminent men have been studied and described, the few including those of Chauncey Wright, Grote, Gauss, Gambetta, Helmholtz, and a few others In the *Philadelphia Medical Journal* of April 6th Dr E A Spitzka gives a description of the brains of two distinguished physicians—father and son. The elder, Dr Edouard Seguin, was born in France in 1812 of a family which had distinguished itself for generations in medicine and the fine arts Seguin became a physician and associated himself with Esquirol in the great work of the humane treatment of lunatics which the latter was then carrying on, devoting himself specially to the care and treatment of idiocy and imbecility For over 40 years he was physician at the Hospice de Bicêtre and published works which immediately assumed a classical importance in regard to the subject of the education and treatment of the feeble minded and the imbecile He died in October, 1880 His son, Professor Edward Constant Seguin, was born in 1843, and after pursuing his medical studies in New York was appointed lecturer on diseases of the nervous system and insanity at the College of Physicians and Surgeons, New York, in 1871 He made valuable and original contributions to the pathology and therapeutics of nervous disorders and was one of the pioneers of American neurology He died in February, 1898 The brain of the elder Seguin, says Dr Spitzka, was normal in appearance and texture and weighed 1257 grammes, the weight being slightly below the average, a condition which Dr Spitzka thinks may have been due to "some wasting of the brain tissue from disease or age, or both" Its characteristic features are summed up as follows (1) marked development with great breadth and fulness of the frontal lobes, (2) a great width and ample development of the parietal and temporal lobes; (3) relative smallness of the cuneus on both sides, especially the left, (4) general tortuosity of the fissures and gyri, (5) an exceptionally full development of the insula, and especially of its anterior part, so that on one side (the left) this part of the insula was not covered by the operculum but remained exposed, and (6) the frontal gyri were the most complex of the entire brain, being particularly rich in their windings The speech centre of Broca was also very well developed "There is that in the 'physiognomy' of the brain, as in the son's," says Dr Spitzka "which it would be impossible to describe otherwise than to say that it portrays the culture, refinement, and intellectual capacity of its erstwhile owner when living" The brain of the younger Seguin weighed 1502 grammes, the right hemisphere being 642 grammes and the left 653 As in the father's brain there was a slight but unquestionable exposure of the anterior part of the left insula There was ample development of the frontal lobes and relatively small development of the occipital lobes Hitherto an uncovered insula has only been found in the brains of imbeciles and mentally defective persons and in negroes, this condition being associated with insufficient development of the opercula. In the case of the Seguins, however, the explanation is different The opercular regions are by no means defective in development, but are well developed The insula, however, has been the seat of exceptionally marked development so that it has "virtually thrust apart the opercula and made itself visible" This view of the relative hypertrophy of the insula is supported by an elaborate series of measurements made of the fissures in and around it Dr Spitzka wishes to correlate this with the exceptional linguistic capacity of the Seguins, both father and son being fluent speakers and writers of three languages—English, French, and German

SIMULATION OF BERI-BERI

A CORRESPONDENT informs us that in the Malay Archipelago there exists a practice of malingering by shamming beri beri which it is almost impossible to diagnose from the real case It occurs mostly in the prisons amongst the long sentence men who are liberated upon showing symptoms of beri beri and are sent to their native home to die there No sooner have they arrived there, however, than they are cured Œdema is produced in a very simple manner A fine hole is drilled into the leg and a small hair is inserted. After the skin has grown over the aperture thus made swelling sets in which pits exactly like the œdema in the real cases, Great lassitude and feebleness follow The Government is only too glad to save the patient's keep and he is sent off home where he soon recovers after he has removed the hair from his leg Medical officers belonging to the services might find it useful to keep this in mind when visiting these countries for the first time

ASTEREOGNOSIS

DR CHARLES W. BURR, neurologist to the Philadelphia Hospital, reports in the March number of the *American Journal of the Medical Sciences* a number of cases which throw light on the interesting clinical condition known as stereognosis to which reference had previously been made in these columns [1] Stereognosis is the capacity of recognising the nature of objects by handling them with the fingers; it is thus a complex perception dependent on the proper coöperation of cutaneous sensations (tactile and pressure sensations) and of the kinæsthetic sense (sense of spatial disposition of the fingers), and to a less extent of temperature and pain sense According to Dr Joseph Sailer [2] the cerebral centre concerned in the function of stereognosis is situated in the parietal lobe of the brain The cases reported by Dr Burr are as follows Case 1—A young man who when a boy sustained a fracture of the right parietal bone suffered from temporary hemiplegia and hemianæsthesia of the left side On recovery he found that he could not recognise objects with his left hand. "On examination years after the injury it was found that though there was no palsy and no anæsthesia, save the inability to localise sensations, he could not recognise any object in the left hand . The explanation was that being unable to localise sensations he could not distinguish form" Case 2—A man, aged 37 years, had suffered for some weeks from "thickness" of speech and a little weakness and stiffness of the left side of the face He then had an attack of illness of an obscure kind attended with unconsciousness, after which he exhibited a slight left-sided hemiplegia Movements of the left arm were weakened There was a slight impairment of tactile sensibility in the left thumb and index finger, and he localised light touch incorrectly but pressure correctly In the left hand there was complete astereognosis.

---

[1] THE LANCET, April 15th, 1899, p 1044

[2] THE LANCET, 1899, loc. cit.

At his death, a few months later, a tumour was found in the right centrum semi-ovale above the lateral ventricle. Cases 3 and 4 occurred in a man and a woman respectively, the diagnosis in the latter being difficult owing to complications of the nature of hysteria. The man, aged 52 years, had astereognosis, and after death a tumour was discovered in the parietal lobe on the left side of the brain. It pressed against, but did not invade, the ascending parietal convolution, partially destroyed the angular gyrus, and involved almost the entire posterior parietal lobule. The subcortical white matter was destroyed by it. Its growth was marked by successive stages of clinical symptoms of a most interesting character, commencing with slight hemiplegia, slight tactile anæsthesia, and astereognosis. This showed that it involved the parietal lobe. Later, as the tumour increased, there followed symptoms of word-blindness (involvement of the angular gyrus) and of amnesic aphasia in varying degrees. The final stages were mental dulness and death. The lesion in this case was adequate to explain both the astereognosis and the word-blindness which were present and to prove the close proximity to each other of the cerebral centres which subserved these functions.

"LEGISLATION ON PENNY ICES: A GOOD EXAMPLE."

WITH reference to an annotation under this title which appeared in THE LANCET of May 18th, p. 1417, a correspondent tells us that the clause in the Brighton Corporation Bill relating to ice-cream did not pass through the Parliamentary Committee in the form in which it was originally drafted. The Bill contained two clauses, the first inflicting a maximum penalty of 40*s.* on any person causing ice-cream or similar commodities to be manufactured, sold, or stored in any improper place, or exposing such commodity to infection or contamination, or failing to notify any outbreak of infectious disease amongst the persons employed in the business. The second clause followed on the lines of Section 6 of the Order of 1885 relating to Dairies and Milkshops, requiring, as in the case of milk, the registration of each person carrying on the trade of dealer in ice-cream and inflicting a penalty on any person selling such commodity within the borough while unregistered. Objection was taken to the latter clause in the preliminary stages of the Bill and the corporation were advised to withdraw it, and they did so. This, we think, is unfortunate, as the first clause without the second will only be partially operative, the main difficulty in connexion with the business of street-vending of ice-cream being to find the home address and to keep under frequent observation the condition of the house in which the ice-cream is manufactured.

A FRENCH SURGEON-MAJOR'S EXPERIENCE OF BRITISH HOSPITAL SHIPS.

SOME notes from an official report by Surgeon-Major Ropert, of the French frigate *Melpomène*, have recently been published with reference to British sick-transport from the Cape of Good Hope. His ship having put in at Las Palmas Surgeon-Major Ropert had an opportunity of inspecting the *Orotava*, which was conveying invalids to England. He expected to find "complex installations," but on the contrary everything was "very good but very simple." All the first-class cabins having been dismantled, large, well-ventilated, and sufficiently lighted wards were obtained, affording ample cubic space for the soldier-patients who occupied frame beds made of canvas which were suspended from the ceiling. These cots were all on the same plane, and the space between them was more than wide enough for the attendants. The *Orotava* was used for sick-transport only, but the *Lismore Castle*, which was also inspected, had been converted into a hospital ship. Having been sent out to Durban as a transport, her captain received orders at that port to fit his vessel out for the accommodation of sick and wounded men, and six days afterwards he was able to embark the patients. During upwards of four months the vessel had served admirably as a floating hospital, and she was now *en route* for England with every berth occupied. The installation, "as simple as practical," is briefly described by Dr. Cassien, who was one of Surgeon-Major Ropert's subalterns. It was apparently quite perfect, comprising luxurious quarters for 162 incapacitated soldiers, sick, wounded, and convalescent, besides a number of beds for non-commissioned officers in the side cabins, and for officers in the smoking-saloon and elsewhere on the upper deck. In close proximity to every ward there were baths, water-closets, and ice-chambers. The operating-room on deck was constructed of planking lined with tarred canvas and covered by a double roof. It contained a receptacle for instruments, another for dressing material, a large washing-stand with an electrically heated boiler, and several moveable incandescent lamps. "This simple little room, small and so easily disinfected, seemed to us," says Dr. Cassien, "to fulfil all the conditions requisite for the successful issue of the operations which, to the number of eight per week, had to be performed during the voyage." The solitary blot mentioned by Dr. Cassien is in connexion with the x ray installation. The radiographs produced were of little practical utility, although doubtless, he adds, "their moral effect on some of the wounded may have been advantageous." The professional service on the *Lismore Castle* was performed by five surgeons who had been engaged for the voyage, as well as by the medical officer of the ship. Five nurses "belonging to honourable Cape families" are described as volunteers, although they received pay at the rate of £100 a year with an additional allowance of one and a half francs to cover their daily expenses; 30 male attendants and two compounders completed the medical establishment. The lifts provided at each of the hatchways, which were capable of raising or lowering a patient while lying at full length in his cot, excited the admiration of Dr. Cassien, who was also favourably impressed by the way the gradient of the companion ladders had been adjusted to meet the requirements of the invalids. "A *monte-charge* (lift)," he says in conclusion, "is an installation which seems to me to be worthy of retention. It is not a fixture and can be readily installed when required."

THE EFFECT OF INTERCURRENT DISEASES ON EPILEPSY.

DR. JULES VOISIN of the Salpêtrière, *Paris*, contributes to the *Semaine Médicale* of March 20th a valuable article based on a large number of observations as regards the effects of intercurrent diseases on the course and prognosis of epilepsy. The following are the chief conclusions obtained as regards the epileptic attacks. 1. The epileptic seizures are lessened in frequency or restrained by an intercurrent attack of erysipelas during the acute stage of the latter, but the fits return during the stage of convalescence. This was noticed in several cases. 2. In one case of anthrax the epileptic fits were absent during the suppurative stage, but the patient died from acute septicæmia. 3. In epileptic patients who have contracted phthisis the fits subside when the tuberculous process is most acute and reappear when the phthisis is ameliorated. This was noted in many cases. 4. In a few cases of diphtheria supervening in the course of epilepsy the fits were absent during the illness but returned during convalescence. 5. In small-pox and in rheumatic fever epileptic fits are diminished during the acute stage only. 6. Epileptic attacks are rendered worse and *more* dangerous in scarlet fever Four epileptics contracted *scarlet fever* and all died on the fourth or fifth day of *illness*, whereas 15 other patients in Voisin's Clinic who contracted scarlet fever and who were *non epileptic* all recovered uneventfully 7. Influenza greatly increases *the* number of epileptic attacks, and its pulmonary complications exert a dangerous effect on epileptics Influenza *tends* to produce the status epilepticus Thus one patient so affected *had 175 fits* in five days and another had the extraordinary *number* of 214 fits in *one day* This *deleterious result has* also been *fully* shown in a recent *these* by Dr Lannois of Lyons

THE EARLY DAYS OF "THE LANCET" A BROKEN LINK

THE death in his ninety third year is announced as having taken place at Godalming on May 10th of Mr Alexander Dickson Mills His name will probably recall to those who have read the "Life and Times of Thomas Wakley" the very early days of THE LANCET'S existence Thomas Wakley's biographer writes on page 223, &c "A few words should be said of Wakley's staff during the first 10 years of THE LANCET, *for had* he not been loyally supported by his assistants he never could have accomplished what he did during the period or have laid the foundation for his great success in the future From the beginning he was helped by Cobbett and Wardrop, but on the paper being transferred to the offices of Messrs Mills, Jowett, and Mills he was introduced to a family with whom he was to remain for many years in *close* contact, and whose assistance to THE LANCET *can* be over estimated with difficulty Mr Mills, senior, had four sons—Samuel, George Ireland, James Basnett, and Alexander Dickson Samuel was in his father's firm and became the head printer to THE LANCET, while the three younger sons joined the staff in different capacities George Ireland Mills *succeeded* to much of Lambert's editorial work *when that* gentleman retired from the staff after the Bransby Cooper case He later became Wakley's *private secretary*, and was for some time his deputy *coroner* James Basnett Mills was a very fine young *scholar* He frequently acted as Wakley's *amanuensis* He eventually took orders, and was classical coach to no less a person than Benjamin Jowett, the *famous* Master of Balliol, who was a son of the partner in the firm of Mills, Jowett, and Mills, while his next *pupil* was Wakley's eldest son Alexander was a proof reader in the establishment when the printing of THE LANCET was removed to Bolt court He was the first *sub-editor* of the paper, and combined the duties *with those* of publisher Alexander Mills's room *formed* the business office of THE LANCET, and here the *meetings of* the staff took place on Friday nights " The task of obtaining materials for the biography was very materially assisted by Mr Alexander Dickson *Mills*, who most kindly lent to us a great many old papers and letters which we could not otherwise have obtained, notably the letter from the founder of THE LANCET to Douglas Jerrold which is printed on p 493 of the *book* Mr Mills until quite recently, at all events, despite his great age, was vigorous and hearty.

THE X RAYS IN THE *DIAGNOSIS* OF THORACIC ANEURYSM

IN the *Edinburgh Medical Journal* for April Dr Hugh Walsham shows the great value of skiagraphy in the diagnosis of thoracic aneurysm In all *doubtful* cases of chest disease a skiagram, he thinks, should be taken Dr Walsham uses a coil giving a 12 inch *spark* The secondary coil has some 15 miles of wire *wound* in 70 sections and is worked by 24 cell accumulators *of* 21 ampere hours' capacity and an electro motive *force* of 16 volts The time of exposure depends a good deal on the patient For obvious reasons fat and muscular persons require a longer exposure than *thin ones*, adults and males *require a longer* exposure than children and females For thin patients about one minute 50 seconds is sufficient, for very muscular patients three or four minutes may be required A knowledge of the normal shadows of the heart and aorta is necessary before skiagrams can be interpreted Normally the *shadows* of the heart *and* aorta are well seen, *and that* of the *aorta* can be traced *up* nearly to the manubrium sterni Dr Walsham relates the following cases in which thoracic aneurysm was first discovered by skiagraphy Case 1 —A man, aged 45 years, had been treated by three physicians *for* intercostal neuralgia The upper dorsal vertebræ were tender on percussion There were no dulness, tracheal tugging, inequality of pupils, or cough, *and* there *was* only slight dyspnœa *Radioscopy* showed a large aneurysm of the thoracic aorta Case 2 —A woman, aged 51 years, was admitted to hospital in 1897 with signs of aortic regurgitation and was discharged considerably improved She returned in 1900 in much the same condition, but pain in the back *from* which *she had* previously suffered was much *worse* *Radioscopy* showed an aneurysm of the descending aorta Case *3* —A woman, aged 58 years, was sent to hospital with the diagnosis of laryngeal phthisis Laryngoscopic examination showed paralysis of the left vocal cord, but this was the only sign of aneurysm Radioscopy showed a large aneurysm of the transverse arch *of* the aorta Case *4 —A man*, *aged* 37 years, was admitted *to* hospital *and* intra thoracic tumour was diagnosed A skiagram showed a large aneurysm of the aorta As an aid in prognosis *skiagraphy* is also useful Fluid blood is almost completely transparent to the x rays, clotted blood is *comparatively* opaque The greater the opacity of the aneurysm the more abundant, therefore, is *the* laminated clot contained *in it*

THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN

PHARMACISTS have many topics to discuss *just now*, and at the annual dinner of the members of the Pharmaceutical Society held on May *21st* at the *Hôtel* Métropole some important expressions of *opinion* were made in regard to the position of pharmacy and the pharmacist In speaking to the toast of the evening—viz, "The Pharmaceutical Society of Great Britain"—Sir James Crichton Browne, F R S, Vice President of the Royal Institution, said that the work of the pharmacist was *to perfect*, to improve, and to disseminate *means of* alleviating suffering and prolonging life This work was hampered by ignorance and prejudice which must be overcome by education The work of improving the education of chemists and druggists and of maintaining discipline among them was one which was an advantage to the *whole* community and therefore deserved public *support* It had been whispered that the days of *medical men* and druggists were numbered and that faith healing was to reign supreme Though faith healing had been taken up by a certain number of persons of ill balanced minds it was the most blatant and hideous infidelity, ostensibly founded on certain texts but totally ignoring the revelation of the book of nature which was constantly being unfolded by science and teaching the sources of human ills and their appropriate antidotes He believed and knew that notwithstanding the success of the Pharmaceutical Society some *of* its members had a hard struggle, and he *considered* that they should be protected as far as *possible from* all undue competition He therefore ventured to suggest that at some convenient time the

Pharmaceutical Society should direct its attention to the sale of drugs in hospitals to out-patients. He was not desiring to limit the free supply of medicine to the poor, but there was no justification for using charitable funds to take the bread out of the mouth of the poor pharmacist, because if an out-patient could afford to pay for medicine the pharmacist was the proper person to receive the money. Many an out-patient would be the better for some good port wine but he had not heard that any hospital had yet opened a bar or applied for a licence to sell liquor on their premises. The toast of "The Medical Profession" was entrusted to the care of the treasurer of the society, Mr. S. R. Atkins, who said that the society had always tried to inculcate in its members a very high line of conduct. He thought that all would agree that medicine was the only profession apart from the Church which was truly altruistic. Dr. D. MacAlister, chairman of the Pharmacopœia Committee of the General Medical Council, in acknowledging the toast said that he had been for many years endeavouring to bring the British Pharmacopœia, which was their common sacred book, into a condition nearer perfection than it had been before. The work was now before the world and he was gratified to find that it had not been unsuccessful and any success which had been gained was due to the fact that the General Medical Council had been in very close relation with the Pharmaceutical Society in the preparation of the volume. Mr. W. Palmer, M.P, in responding to the toast of "The Houses of Parliament," said that he hoped to be able to promote the interests of the society in connexion with any legislation which might come before Parliament. The banquet was very largely attended, over 200 guests being present, amongst them being Sir Frederick Abel, Bart., F.R S., director of the Imperial Institute; Mr. A. Curtis Cope, of the Royal College of Veterinary Surgeons; Professor J. M. Thomson, F.R S., of the Institute of Chemistry; Professor W. A. Tilden, F.R.S, and Professor N. Collie, F.R.S.

A JUDGE AND JURY ON INFANT INSURANCE

THE connexion between infant mortality and insurance has been often observed, and under such conditions as to suggest, at times very strongly, that there frequently exists between them a relation which is practically that of cause and effect. This was the view taken by a jury which recently returned a verdict of manslaughter against a woman at Darwen. They used the opportunity to express their condemnation of the way in which insurance companies paid premiums on the deaths of children over the age of six months. The presiding judge, Mr. Justice Darling, referred to this practice as one which simply offered a premium to parents to neglect their children or to ensure that they should die at six months. It is refreshing to find a judge and jury express themselves with so much candour and directness, and we believe that no disinterested and honest thinker who has really given his attention to this subject will be disposed to dissent from these views We confess that we have never been able to see the necessity for this system of insurance in our social organisation. The burial of an infant is very far from being a costly matter. It ought to be quite within the scope of thrifty management on the part of even poor parents. It is notorious, moreover, that the sums insured for are often far beyond those required for mere funeral expenses. Equally certain is it that the insurance premiums would in very many, probably in most, cases be allowed to lapse if it were not for the solicitous energy of the agents who collect these subscriptions for the companies they represent. The whole arrangement wears to our mind the aspect of a business venture, not too nice as to its methods. We are thankful, therefore, to a judge and jury who have spoken their minds, and we sincerely hope that a Government which has the country at its back will take up this question in a similar spirit. One consequence of such action will be a diminution in the present rate of infant mortality.

PLAGUE AT THE CAPE OF GOOD HOPE.

A TELEGRAM received at the Colonial Office on May 17th gives the following statistics of plague for the week ending May 11th:—Europeans, eight cases and two deaths; coloured persons, 24 cases and 19 deaths; Malays, five cases and four deaths; East Indians, no cases or deaths; Chinese, no cases or deaths; natives, one case, no death. Total for the week, 38 cases, 25 deaths. The total cases and deaths up to May 11th are as follows:—Europeans, 155 cases and 50 deaths; coloured persons, 280 cases and 138 deaths; Malays, 39 cases and 30 deaths; East Indians, five cases and five deaths; Chinese, one case and no death; natives, 130 cases and 52 deaths. Total up to May 11th, 610 cases and 275 deaths. Four cases have been notified at Port Elizabeth.

THE ROYAL UNIVERSITY OF IRELAND.

SOME amusement has been caused in the medical profession in Ireland by certain proceedings at the Senate of the Royal University on May 3rd, the nature of which has transpired sufficiently to allow a judgment to be formed. The facts are simply as follows. The question of the desirability of appointing extern examiners as in other universities has been before the Senate for about two years. A strong committee reported on the question and the Senate at a large meeting in February adopted the report recommending the appointment of extern examiners in surgery, midwifery, pathology, and ophthalmology; yet it is common knowledge that at a small meeting of the Senate on May 3rd (without any previous notice on the agenda paper) it was agreed in substance that no further steps should be taken as to the appointment of extern examiners till Dr. W. A. McKeown and Professor T. Sinclair, who had moved in the matter, should define what was meant by the term "extern" The Senate were led in this matter, which seemed to be a purely medical one, by the opinion of the medical members who chanced to be present. The action of the Senate means that the Belfast medical representatives are to travel to Dublin to define the meaning of a word in common use in universities. The question of extern examiners is not merely a medical one; it is a general one The failings of county councils and of boards of guardians in the conduct of business might be passed over, but that the senate of a university should have discussed for two years the appointment of "extern" examiners, and after having agreed to make such appointments should admit that they do not know what they have been talking about, is to the ordinary mind incomprehensible, especially when every one of them is supposed to be intimately acquainted with university terms and practices. To anyone who knows the medical schools of Ireland and the peculiar constitution of the medical examining boards of the Royal University as well as the extent to which some medical examiners have been in the habit of asking questions to which sufficient answers can only be given by students who have been taught by themselves, the meaning of the word "extern" can hardly be misunderstood. It means, in fact, that any person connected with any university, college, or hospital in Ireland should not be eligible. It is further felt that, in the public interest, extern examiners should be appointed for the medical examinations in Trinity College, Dublin, the Royal College of Surgeons in Ireland, and the Royal College of Physicians of Ireland. The standard of the Royal University of Ireland is high, but that of the institutions named is not always satisfactory. Only in this way can the malign influence of examining after merely local traditions, ideas, and practices, too common in Ireland, be effectually and for ever killed.

THE CARE OF NEGLECTED CHILDREN IN THE UNITED STATES.

AN interesting report has been issued recently by the Children's Aid Society of Philadelphia which completes the nineteenth year of its existence as a philanthropic institution. The work of the society includes the care and bringing up of foundlings and "neglected children." The report shows that at the beginning of the year 1900 803 children were under care, and that 140 fresh cases were received during the course of the year. The children were taken from various classes and strata of society and included the following · orphans, 33 ; half-orphans, 97 ; deserted children, 39 ; children of dissolute parents, 63 ; children of unmarried parents, 43 ; children of invalid or insane parents, 26 ; children rescued from ill-treatment, 88 ; children of parents living but separated, 93 ; children of parents who could not control them, 42 ; vagrants, 10 ; children received from criminal courts by magisterial orders, 56 ; children from almshouses, 335 ; and children from other charitable societies, 18. Depravity and immorality, often combined with disease and dirt, were generally found to be among the circumstances in which most of the children began life, and the report states that taking the little ones from their noxious surroundings, housing them with kindly foster-parents, and educating them in order to enable them to earn a living constituted the only means of saving many from the prison or workhouse—a service which, unobtrusively pursued, was of inestimable value to the community. The success achieved by the Philadelphia Children's Aid Society must be regarded as worthy not only of praise but of emulation.

PROSPECTS IN GENITO-URINARY SURGERY.

IN an address on this subject delivered at Cornell University, U S A , Mr. Reginald Harrison touched many points of great interest Allusion to the great advance made by Bigelow in the discovery of the operation of litholapaxy, which was no doubt influenced by the investigations of another American surgeon (Otis) into the size of the male urethra, formed an appropriate introduction to his lecture Bigelow's operation has one disadvantage—it is liable to be followed by recurrence of stone. This leads to the question of calculus formation, a subject first investigated by Rainey of St. Thomas's Hospital, who as far back as 1857 demonstrated a method of making calculi artificially by what he described as "molecular coalescence" The more recent work of Dr. Vandyke Carter and Dr. W. M. Ord has confirmed and extended his views. From these investigations Mr. Harrison concludes that for the artificial production of calculi by molecular coalescence precision in regard to details is necessary. The repetition of Rainey's experiments and their development with a view to discovering methods of preventing the formation of calculi and of cure in cases in which they have formed constitute, as Mr. Harrison suggests, work which might well engage the attention of laboratory workers. Turning to the subject of "enlarged prostate" he pointed out that from the therapeutic standpoint this term is beginning to be recognised as too vague. When micturition is seriously interfered with and the condition is unmanageable by the catheter the precise nature, shape, and relations of the prostate can now be determined by the cystoscope preliminarily to surgical treatment—a procedure of great advantage. For example, in a case of rapidly recurring stone in the bladder it was found by cystoscopic examination, before repeating Bigelow's operation for the third time within two months, that a pedunculated process of prostatic tissue, just to be detected by rectal examination, had converted practically the lower and posterior segment of the bladder into a box with a moveable lid formed by the prostate. This by confining a certain quantity of urine brought about its decomposition and led to the formation of a phosphatic stone Thus the calculus was simply a natural result of the condition of the parts. Mr. Harrison practised the median perineal *boutonnière* operation and twisted off the narrow-necked growth. There are three varieties of enlarged prostate which require different treatment General hypertrophy, usually associated with congestion, gives good results when treated by vasectomy, castration, and possibly by Bottini's operation. A pendulous prostatic growth is not suited to any of these operations but is best treated in the manner just described Obstruction depending on the presence of an interstitial adenoma has been most successfully dealt with by enucleation through a suprapubic incision.

RETIREMENT OF THE DIRECTOR-GENERAL, A M S.

WE understand that Surgeon-General J. Jameson, C.B., Director General of the Army Medical Service, is retiring on June 1st next with the maximum pension. The occasion will, we hope, afford a fitting opportunity for giving to the retiring officer the titular distinction which was anticipated for him in the recent Gazette

WE have reason to hope that the report of the Commission of Inquiry into the management of the National Hospital for the Paralysed and Epileptic, Queen square, will be found very satisfactory for the cause of representation of the medical staff on the board. The Commission closed its sitting last week and the report will soon be published.

THE forty-first annual dinner of King's College, London, will be held at the Trocadéro Restaurant, on Monday, June 24th, the Hon. Mr. Justice Byrne in the chair. Communications should be made to Mr. John Chapman, honorary secretary of the committee.

To the names of medical candidates for the coronership of the City of London there should be added that of Mr. G. Russell Beardmore, who is also a barrister-at-law.

MEDICAL MEN AND THE WORKMEN'S COMPENSATION ACTS.

II [1]

As we pointed out in our first article the medical practitioner has duties imposed upon him by the Workmen's Compensation Act of 1897 beyond those which consist in attending or examining a man injured in an accident, and giving evidence either on his behalf or that of his employer at the trial of an action for compensation. These duties are defined, not in the Act, which is a short one, but in the schedules and regulations appended to it. In the Act itself we see nothing, beyond what we have already mentioned, that concerns medical men even indirectly, except possibly the proviso that before proceedings are taken under the Act notice must be given to the employer of the accident, and that this notice must be given "as soon as practicable after the happening" of the accident, or in any case within six months of the happening of it, or, where death has resulted, within six months of the death. Sometimes, perhaps, the question whether it was practicable for this notice to be given earlier may call for medical evidence. The notice, however, need not necessarily be given by the victim of the accident himself if he be alive, but is naturally given in many cases by his friends. It must, besides giving the injured man's name and address, "state in ordinary language the cause of the injury and the date at which it was sustained." It should evidently be in writing, although nothing is said expressly on this point, and it will be noted that no mention is made of any statement in it as to the nature and extent of the injuries sustained. The next step prescribed arises under the third section of the first schedule, which runs as follows:—

---

[1] Part I. appeared in THE LANCET of May 18th, 1901, p. 1420.

> *Schedule I. (3).*—Where a workman has given notice of an accident he shall, if so required by the employer, submit himself for examination by a duly qualified medical practitioner provided and paid by the employer, and if he refuses to submit himself to such examination, or in any way obstructs the same, his right to compensation and any proceeding under this Act in relation to compensation shall be suspended until such examination takes place.

It will be observed that this examination must be by a duly qualified practitioner, which means one duly registered, and the nature of the examination and of the evidence that will have to follow it will be gathered from what follows as to the scale of compensation. It is not necessarily a final examination, in that there may be subsequent examinations, to which we shall refer, which may corroborate or correct the conclusion arrived at. It will be noted that the medical practitioner employed under this section is to be "provided and paid by the employer." In cases in which payment is not made before the examination takes place it is advisable for the medical man who wishes to prevent subsequent disputes to be sure that the employer has "provided" him and is aware of his liability towards him.

The amount of compensation may be agreed between the employer and the workman or his representatives. Subject to such agreement it is to be settled by arbitration, the county-court judge being the usual arbitrator. It may be mentioned, in passing, that the county-court judge and the arbitrator appointed by him have power to compel the attendance of witnesses and the production of documents as if the matter were an action in the county court. With the assessment of compensation where death has occurred the medical practitioner, as a rule, has little to do and his evidence will be confined to the fact of death and its cause. In the case, however, of a deceased person who has left no dependents the reasonable expenses of his medical attendance and burial, not exceeding £10, can be recovered as compensation under Schedule I. (1. A. iii.). On this contingency occurring the legal personal representative of the deceased person is the proper person to apply for the settlement of the claim by arbitration and if there be no such representative then any person to whom such expenses are due should apply. Such applicant must join as applicant or respondent any other persons to whom he knows such expenses are due. If the amount awarded is not sufficient to pay all claims in full the amount awarded will be apportioned by the judge or arbitrator (see Workmen's Compensation Rules, 6). In the case where an injured workman is entitled to compensation for injuries which have not proved fatal the details of the method by which the payments ordered to be made to him are calculated do not concern the medical practitioner. It is enough for him to know that the compensation is based upon weekly earnings and is to compensate for weekly earnings lost during the period of incapacity which follows the first two weeks of such incapacity. For the first two weeks after the accident the Act does not compensate the injured man, and the compensation takes no account of pain and suffering such as are reckoned in assessing damages at common law or under the Employers' Liability Act, nor does it include expenses of medical attendance. We have seen the extent to which these last are provided for in the case of death. The compensation when fixed is paid weekly and the 11th section of Schedule I. provides as follows:—

> *Schedule I (11).*—Any workman receiving weekly payments under this Act shall, if so required by the employer, or by any person by whom the employer is entitled under this Act to be indemnified, from time to time submit himself for examination by a duly qualified medical practitioner provided and paid by the employer or such other person; but if the workman objects to an examination by that medical practitioner, or is dissatisfied by the certificate of such practitioner upon his condition when communicated to him, he may submit himself for examination to one of the medical practitioners appointed for the purposes of this Act, as mentioned in the second schedule to this Act, and the certificate of that medical practitioner as to the condition of the workman at the time of the examination shall be given to the employer and workman and shall be conclusive evidence of that condition. If the workman refuses to submit himself to such examination or in any way obstructs the same his right to such weekly payments shall be suspended until such examination has taken place.

The rules which govern reference to medical referees prescribe that such references as they deal with shall be made through the county court only. The section above quoted is framed to provide for the workman going in the circumstances described direct to the referee. In such a case the referee will have to look to the workman for a reasonable fee and should receive it before making his examination (Home Office Memorandum, dated April 19th, 1898). It will be noted that this section provides against a man who has been awarded compensation malingering and exaggerating the duration of his incapacity for work and that it enables not only the employer to have the workman re-examined by a medical man, but also enables a person to do so by whom the employer is entitled to be indemnified—that is to say, in most cases, the insurance company with whom the employer has insured against this class of risk, or in other cases a stranger who has by his negligence contributed towards the accident.

The twelfth section of Schedule I. provides that:—

> Any weekly payment may be reviewed at the request either of the employer or of the workman, and on such review may be ended, diminished, or increased subject to the maximum above provided, and the amount of payment shall in default of agreement be settled by arbitration under this Act.

With regard to this we need hardly point out that the discontinuance, increase, or diminution of the weekly payments must depend chiefly upon what the medical practitioner has to say with regard to the workman's capacity for labour, and that the last word as to this will rest with the medical referee where there is a difference of opinion on the part of those who give evidence on his behalf or that of his employer. The employer only, and not the persons who indemnify him, is entitled, apparently, to the benefit of this last-quoted section.

ASYLUM REPORTS.

City of London Asylum, Stone, near Dartford (Annual Report for 1900).—The average number of patients resident during the year was 498 and comprised 244 males and 254 females, showing an increase of 13 as compared with 1899. During the year 184 patients were admitted, of whom 108 were males and 76 were females. Dr. Ernest W. White, the medical superintendent, states in his report that "this is the largest number of admissions in one year since the opening of the asylum." Seven of the males and 10 females were readmissions. As regards bodily health 43 males and 30 females were weak, while four males and seven females were in bad health. Regarding the mental condition of the 184 patients admitted five males and two females were suffering from general paralysis of the insane, 27 males and 15 females from the more acute forms of mania, and 18 males and 19 females from acute melancholia. The admissions included 18 cases of chronic mental disease. As regards the causation of insanity in the admissions, heredity, intemperance, and previous attacks were the chief factors, after which followed such conditions as old age, worry and anxiety, and bodily diseases. The number of patients discharged as recovered during the year was 74—viz , 49 males and 25 females, or 14 8 per cent. of the average number resident The recovery-rate has been reduced somewhat by the chronic cases admitted as mentioned above. The deaths during the year amounted to 31, including 16 males and 15 females, or 6 2 per cent. of the average number resident. Of the 31 deaths four resulted from general paralysis of the insane, four from chronic Bright's disease, four from melancholia, three from mania, four from pulmonary tuberculosis, three from epilepsy, and three from senile decay. The casualties consisted of one case of dislocation of the shoulder by a fall, one of fracture of the left femur in a patient pushed down by another, one of fracture of the forearm by a fall, and one of a fractured rib caused by a blow from a patient. Four patients escaped but all were brought back to the asylum within 24 hours of escaping. Forty-eight paying patients are accommodated in the asylum, 23 being males and 25 females. The system of having paying patients continues to show success. The general health of the institution was good

Epidemics of influenza broke out in October and in January affecting both patients and staff In January there were three cases of enteric fever and in May two cases, the patients in all of which cases recovered Ulcerative colitis did not occur in a single case The working of the farm for the year showed a net profit of £452 10s The live stock were healthy during the year, 491 head of poultry were reared and over 27 000 fresh eggs were received from the farm during the year The Lunacy Commissioners state in their report that the post mortem records and case books are intelligently kept

Barnwood House Hospital for the Insane, near Gloucester (*Annual Report for 1900*) —The average number of patients resident during the year was 153, and comprised 63 males and 90 females 27 patients were admitted during the year, this being the smallest number admitted in any year since 1891 The average admission rate for the five years beginning 1895 was 34 6 Dr J G Soutar, the medical superintendent, states in his report that many of the cases admitted were of an unpromising nature as far as recovery was concerned, 11 of the 27 being regarded as incurable Two patients came to the hospital as voluntary boarders, but it was found necessary to place them under certificates Applications have often been received for the admission of other voluntary boarders, comparatively few of whom, however, were regarded as suitable These applicants were of two kinds first, those whose mental ailments was so slight that, in the interest of the patients, it was necessary to advise that other methods of treatment should be followed "rather than that they should be subjected to the somewhat depressing circumstances and influences which even with the strictest classification, are in some degree inevitable in an asylum', secondly, those patients whose friends desired to place them in an asylum, but without certification, on the plea that the illness was "hysterical" or due to "eccentricity,' whereas the true mental state was either that of mania or of delusional insanity The alleged causes of insanity in those admitted were "as varied and as unsatisfactory as usual," but in 37 per cent of the cases an hereditary tendency to mental disorder was ascertained to exist and in many of the "recent' cases there was marked failure of the general health During the year nine patients—five males and four females—were discharged as recovered, or 5 8 per cent of the average number resident "This compares unfavourably with the recovery rate for 1899 We have to go back to 1882 to find a year in which the percentage of recoveries on admissions was so low as it was in 1900' The explanation of this fact is that there have been very few cases of acute and curable insanity among the admissions Two female patients were discharged to their homes as relieved, and 13 patients were discharged as not improved The deaths during the year amounted to seven (four males and three females), or 4 57 per cent of the average number resident Of the deaths one each was due to phthisis, intestinal obstruction, and cardiac disease, and two each to pneumonia and general paralysis The only casualty of a serious nature was a fracture of the thigh sustained by an old female patient from an accidental fall There were no outbreaks of infectious diseases during the year and the general health of the patients and the staff was good No structural alterations were made in the hospital during the year, but the usual attention was given to repairs, decorations, and furnishing Of 10 male attendants one died two were called up for service in South Africa, two were dismissed for breach of discipline, and five left by their own wish Only four female attendants left during the year —three of these left to be married The Lunacy Commissioners state in their report that the medical case books were well and carefully kept They were of opinion that a Turkish bath would prove a useful addition to the hospital

PROVISIONAL RETURNS OF THE CENSUS OF 1901.

II[1]

THE Registrar General has recently issued a further instalment of the census returns, showing the enumerated populations of the several administrative counties of England and Wales The figures for the metropolis and for the English and Welsh county boroughs have already been given in THE LANCET; we are, therefore, now able to show the totals for England and Wales They are as follows —

County of London	4,536 034
Other administrative counties	18,850 492
County boroughs	9,139 190
Total, England and Wales	32 525,716

In the appended table we have worked out the differences in the populations of the several counties at the last two censuses, but the figures must be taken as approximate only and as subject to revision after the enumeration books have been scrutinised at the Census Office The results, however, as herewith presented are believed to be fairly reliable

Since the census of 1891 the population of England and Wales in the aggregate has increased by 3 523,191, or 12 15 per cent, the percentage increase during the preceding intercensal period having been 11 65

It will probably be some considerable time yet before we shall know the comparative rates of increase of "urban" and "rural" England respectively, but if we divide England and Wales into two sections, the one consisting of the 67 county boroughs (including London), and the other of the 62 administrative counties, the returns show that the former areas in the aggregate have increased faster than the latter by fully 1½ per cent Of the 62 administrative counties of England and Wales 48 show an increase of population since the previous census, while 14 show a decrease Of the latter Oxford, Devon, Norfolk, and West Suffolk are the counties the populations of which are apparently declining most rapidly It is probable, however, that the more decidedly rural portions of certain other agricultural counties, such as Wilts, Bedford, Bucks, Somerset, and Dorset, would also show a decrease, perhaps even greater than either of the foregoing, if the numbers living in the urban parts of these counties could be counted separately and eliminated from the totals This, however, cannot be done until the detailed returns of the urban and rural areas are available

In our opinion there is no doubt that a real diminution of population in the purely agricultural districts of England and Wales is in progress, although the figures at present at our disposal do not enable a correct estimate to be formed as to its extent It is in the north western and northern counties and in the home counties of England that the growth of the population since 1891 has been the most rapid Thus, the population of Essex has increased in round numbers by 238 000, that of Middlesex by 249,000, that of Kent by 129 000, and that of Surrey by 100 000 Taking these four counties together, the population has increased in the aggregate from 2 347 808 to 3 064 274, or by more than 717 000

We have before expressed an opinion, which the results of the recent census confirm, that a period of more than five years should not be allowed to intervene between one census and another But even with a quinquennial census it is evident from the metropolitan returns that estimates of the population for subsequent years are frequently unreliable It is, however, obviously desirable, whether or not a census of England in 1906 is decided upon, that some method more efficient than that at present in use of estimating the population for intervening years should be adopted It has before been suggested by competent authority that a true return of inhabited houses in towns of sufficient size would supply a satisfactory basis for such estimates This plan has been tried in past years for a few of the larger English towns, but with only partial success, probably because of local difficulties which were not effectually dealt with at the time We are, however, advised that a competent actuary would readily suggest a form of rate book which would show with sufficient accuracy the number of houses actually occupied in a given town from year to year, and that such a return, whilst subserving the purposes of the local rating authorities, would furnish the means of arriving at a fairly reliable estimate of population For it is well known that when the totals are sufficiently large the average number of persons per house is practically constant for the same town

In the course of a few weeks we hope to receive the preliminary census report complete, which will furnish all the information derivable from the unrevised returns that are made by the local registrars throughout the country

---

[1] The first instalment was noticed in THE LANCET of May 11th 1901 p 1357

*Population Enumerated in 1891 and 1901 in the 62 Administrative Counties of England and Wales.**

Areas.	Population. 1891.	Population. 1901.	Difference in 1901.

THE MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.

THE festival dinner of the Medical Graduates' College and Polyclinic was held at the Hotel Cecil on Wednesday, May 22nd, when the Right Honourable A. J. Balfour, M.P., presided.

The loyal toasts, which were proposed by the chairman, having been duly honoured,

Mr. **BALFOUR** gave the toast of the evening. He said that he proposed the toast with deeper feelings of responsibility than usually oppressed a person in his position, because he knew that he was pleading a cause which had not behind it any great wave of popular feeling or emotion, a cause which did not readily or immediately appeal to the man in the street, and yet it was a cause in which the whole community were deeply and profoundly interested. It was a cause which touched every one of them as human beings and which affected not only their own happiness, their own lives, and the happiness and the lives of those nearest and dearest to them, but the future generation whom it was their business to aid. The "Polyclinic" was an institution which was in this country as yet young, though well known and fully recognised in almost every civilised country in the world. It was an institution with many sides of activity and utility. He would not attempt to dwell upon them all, but there were three which would specially appeal to his audience. The first sign of the activity of this institution might be perhaps described as strictly and directly philanthropic—that is to say, it brought directly home to those most in need of it and to those who could not otherwise afford it medical assistance, medical advice, and medical knowledge which would not under other circumstances be at their command. For the Polyclinic did something which the great hospitals in this country could not do and did not attempt to do. The Polyclinic did give, and hoped to give in ever-increasing measure, to a class who could not otherwise get it, expert medical advice which at present was at the command only of the well-to-do. The Polyclinic was also designed to give opportunities of medical education to those who had gone through the ordinary courses which qualified a man to practise but who had little opportunity of keeping themselves abreast with the ever-growing mass of medical knowledge. There was yet a third branch of the activity of the Polyclinic to which he would venture to call the attention of that audience, and it was perhaps the branch which they in this country were most apt to neglect. The growth of medical knowledge was one of the most remarkable scientific facts of the last half-century, for it was in the last half-century that the medical profession had become not merely admirable masters of the practical art of healing, but acquainted scientifically as well as empirically with the causes of many of those maladies with which they had to deal. Could they, he asked, honestly say that in the great development of medical knowledge and therapeutic science this country had taken the lead which it ought to have taken? When he had made all allowance for the great claims on the gratitude of the world for anæsthetics and antiseptics the fact remained, so far as he could judge, that we could not say as compared with Germany or with France or with Italy that we had done all that perhaps we might have done as pioneers of medical discovery. If the question were to be answered in the negative did they not think that the public, the unprofessional and the unscientific public, were in part to blame for that state of things? Did they think that England had shown a recognition of the duties which fell upon her in this matter? They were proud to say that in this country they left to private enterprise and to private benevolence duties which in other and less fortunate countries were entrusted to the Government That was true, but if that policy was to be successful they must have the private enterprise and private benevolence, and had they shown the possession of those great qualities in that particular to the extent that they ought to have done? Personally he grieved to say that he had no doubt as to the answer that should be given He did not believe that any man who considered the equipment of their universities of their medical schools and of other places of education could honestly say in his heart that they had done enough to equip research with all the costly armoury that research must have in these modern days The richest country in the world lagged behind Germany, France Switzerland, and Italy Was it not disgraceful? Were they too poor or were they too stupid? Did they lack the imagination required to show what these apparently remote and abstract studies did for the happiness of mankind? They could appreciate that which obviously and directly ministered to human advancement and human felicity, but they seemed somehow or another to be deficient in that higher form of imagination, in that longer sight, which recognised in studies deficient in obviously necessary or immediate result the foundation of a knowledge which would give far greater happiness to mankind than any mere immediate material industrial advancement could possibly effect He greatly feared that lacking that imagination they had allowed themselves to flag in the glorious race which was now run by civilised countries in the pursuit of knowledge, and that they had permitted themselves to far too large an extent to depend upon others for those additions to knowledge which surely they might have made for themselves He hoped that the result of that evening might be that the Polyclinic which was devoted to the great cause of research might obtain that assistance which was required to make it the useful institution that it potentially was and that it only required their aid fully and perfectly to become He hoped he had not pleaded in vain, at all events the cause was one in which he firmly believed, and if this country allowed itself to be passed in the race he should regard it as a greater national calamity than the loss of a market here or some national contretemps there He should feel that the highest life of the nation had proved itself inadequate to the national necessities and needs

Sir W BROADBENT, in responding, said that it was impossible to over estimate the gain to the Polyclinic of Mr Balfour s advocacy He was not only leader of the House of Commons but in this country one of the leaders of thought At the Polyclinic no patient was made the subject of experiment which was not as much for the benefit of the patient as of the hospital, and the patient was watched with a vigilance and intelligence which was not possible in the best organised hospital

Mr [illegible] [illegible] ilo was [illegible] world, [illegible] to the [illegible] of their cases if it would be of service to their fellow creatures

The DUKE of MARLBOROUGH then proposed the toast of "The Empire," to which Sir J [illegible] for South Australia, replied, rema [illegible] was essentially an Imperial Instit [illegible] the Mecca of medical lore

Mr LIONEL PHILLIPS also responded, and the "Health of the Chairman," proposed by the BISHOP of LONDON, terminated the proceedings

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

In 33 of the largest English towns 6704 births and 3689 deaths were registered during the week ending May 18th The annual rate of mortality in these towns, which had declined from 20 2 to 16 5 per 1000 in the seven preceding weeks, rose again last week to 16 8 In London the death-rate was 15 8 per 1000, while it averaged 17 4 in the 32 provincial towns The lowest death rates in these towns were 8 9 in Croydon, 12 6 in Brighton, 12 8 in Leicester, and 14 0 in Oldham; the highest rates were 20 0 in Liverpool, 20 7 in Manchester, 22 0 in Sunderland, and 22 1 in Preston The 3689 deaths in these towns included 372 which were referred to the principal zymotic diseases, against 394 and 381 in the two preceding weeks, of these, 150 resulted from whooping cough, 81 from measles, 48 from diarrhœal diseases, 45 from diphtheria, 31 from scarlet fever, 16 from "fever" (principally enteric), and one from small pox No death from any of these diseases occurred last week in Huddersfield, in the other towns they caused the lowest death rates in Plymouth, Norwich, and Newcastle, and the highest rates in Swansea, Salford, Sunderland, and Gateshead The greatest mortality from measles occurred in Portsmouth, Wolverhampton, Birmingham, and Sunderland, and from whooping cough in West Ham, Wolverhampton, Bristol, Birkenhead, Preston, Bradford, Hull, Sunderland, and Gateshead The mortality from scarlet fever, from "fever," and from diarrhœal diseases showed no marked excess in any of the large towns The 45 deaths from diphtheria included 14 in London four in Burnley, four in Leeds, three in Sheffield, and three in West Ham One fatal case of small pox was registered in Liverpool, but not one in any other of the 33 large towns; and no small pox patients were under treatment in any of the Metropolitan Asylums hospitals during the week ending May 18th The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2052 against 1705 and 1913 on the two preceding Saturdays, 323 new cases were admitted during the week, against 198, 371, and 397 in the three preceding weeks The deaths referred to diseases of the respiratory organs in London, which had been 286, 251, and 237 in the three preceding weeks, rose again last week to 249, but were 46 below the corrected average The causes of 30, or 0 8 per cent, of the deaths in the 33 towns last week were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in London, West Ham, Leicester, Bradford, Newcastle, and in 13 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Blackburn, and Sunderland

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in the eight Scotch towns, which had decreased from 24 1 to 19 3 per 1000 in the six preceding weeks, rose again to 20 2 during the week ending May 18th, and was 3 4 in excess of the mean death rate during the same period in the 33 large English towns The rates in the eight Scotch towns ranged from 16 0 in Dundee and 18 9 in Perth and in Paisley to 21 6 in Greenock and 23 5 in Perth The 633 deaths in these towns included 41 which resulted from whooping cough, 18 from diarrhœa, 15 from measles, six from diphtheria, four from "fever," three from small-pox, and two from scarlet fever - In all, 89 deaths were referred to these principal zymotic diseases last week, against 83 and 99 in the two preceding weeks These 89 deaths were equal to an annual rate of 2 8 per 1000, which was 1 1 above the mean rate last week from the same diseases in the 33 large English towns The fatal cases of whooping-cough, which had been 39 and 49 in the two preceding weeks, declined again last week to 41, of which 18 occurred in Glasgow, 14 in Edinburgh, five in Dundee, and two in Leith The deaths from diarrhœa, which had been 12 and 20 in the two preceding weeks, declined again to 18 last week, and included 10 in Glasgow, four in Edinburgh, and two in Dundee The fatal cases of measles, which had been 17 in each of the two preceding weeks, decreased last week to 15 of which nine were registered in Glasgow and four in Edinburgh The deaths from diphtheria, which had been two and four in the two preceding weeks, further rose to six last week, and included four in Glasgow, where two of the four fatal cases of "fever" also occurred The deaths from small pox, which had been three three, and one in the three preceding weeks, rose again to three last week, and were all registered in Glasgow The deaths referred to diseases of the respiratory organs in these towns, which had been 169, 125, and

116 in the three preceding weeks, further declined last week to 101, but were 17 above the number in the corresponding period of last year. The causes of 28, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 29 4, 26·5, and 27·4 per 1000 in the three preceding weeks, was again 27·4 during the week ending May 18th. During the past four weeks the death-rate in the city has averaged 27·7 per 1000, the rates during the same period being 16·6 in London and 22·2 in Edinburgh. The 182 deaths of persons belonging to Dublin registered during the week under notice were equal to the number in the preceding week, and included 10 which were referred to the principal zymotic diseases, against 10, 13, and 15 in the three preceding weeks; of these, eight resulted from whooping-cough, one from "fever," and one from diarrhœa. These 10 deaths were equal to an annual rate of 1·5 per 1000, the zymotic death-rate in London being also 1·5, while in Edinburgh it was 4 0 per 1000. The fatal cases of whooping-cough, which had been eight, nine, and seven, were again eight last week. The 182 deaths in Dublin during the week under notice included 30 of children under one year of age and 46 of persons aged upwards of 60 years; the deaths of infants corresponded with the number in the preceding week, while those of elderly persons showed a slight decline. Nine inquest cases and nine deaths from violence were registered during the week; and 74, or more than two-fifths, of the deaths occurred in public institutions. The causes of nine, or nearly 5 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Inspector-General of Hospitals and Fleets Henry Charles Woods, M.V.O., has been placed on the retired list.

The following appointments are notified:—Fleet Surgeon J. H. Beattie to the *Durham*. Staff Surgeons: R. H. J. Browne to the *Osborne*, and R. H. Nicholson to the *Cressy*. Surgeons: N. H. Harris to the *Cressy*; H. L. Geoghegan to the *Herald*; and W. E. Gribbell to the *Diadem*.

ROYAL ARMY MEDICAL CORPS.

Colonel J. F. Supple, C B., has been transferred from South Africa to India for duty. Major Townsend, Major G. B. Russell, Captain H. A. Hinge, and Captain J. R. McMunn have arrived home from India.

Civil Surgeon Matthias Frederick Foulds to be Lieutenant.

INDIA AND THE INDIAN MEDICAL SERVICES.

The King has approved of the retirement of Lieutenant-Colonel Alexander John Willcocks and Lieutenant-Colonel Hugh McCalman.

VOLUNTEER CORPS.

Artillery: 1st Shropshire and Staffordshire: George Mackie to be Surgeon-Lieutenant. *Rifle:* 2nd Volunteer Battalion the Duke of Cornwall's Light Infantry: Surgeon-Lieutenant J. C. Mackay to be Surgeon-Captain. 3rd Volunteer Battalion the Manchester Regiment: Brigade-Surgeon-Lieutenant-Colonel J. Duncan is borne as Supernumerary whilst serving with the Royal Army Medical Corps in South Africa.

VOLUNTEER INFANTRY BRIGADE.

Clyde: Surgeon-Lieutenant-Colonel W. Wilson, 1st Volunteer Battalion the Royal Scots Fusiliers, to be Brigade-Surgeon-Lieutenant-Colonel on appointment as Senior Medical Officer to the Brigade.

SOUTH AFRICAN WAR NOTES.

Major C. C. Reilly, R.A.M.C., Lieutenant E. P. Hewitt, R.A.M.C., Lieutenant R. W. Michell, R.A.M.C., and Lieutenant J. Davies, M.M.S.C., are on passage home.

The following officers have arrived in England from South Africa: Surgeon-Major W. R. Crooke-Lawless, Coldstream Guards; Civil Surgeons J. Bruce, E. W. R. Crossland, H. W. Bruce, E. Mitchell, and A. H. Kirkman.

The following officers have been discharged from hospital for duty.—Captain G. S. McLoughlin, R A M.C., Captain H. G. Martin, R.A.M.C. Tasmanian Bushmen: Surgeon A. B. Browther and Surgeon C. Mattie

The condition of Civil Surgeon Sowden is reported to be unchanged.

It is proposed to inaugurate a stationary hospital of 50 beds at the Yeomanry depôt, Elandsfontein.

VOLUNTEER MEDICAL STAFF CORPS, LONDON COMPANIES: DINNER TO MEMBERS RETURNED FROM SOUTH AFRICA.

Surgeon-Lieutenant-Colonel J. E. Squire and the officers, non-commissioned officers, and men of the London companies of the Volunteer Medical Staff Corps, on Saturday evening, May 18th, gave a dinner at the Holborn Restaurant to welcome home the members of the corps who have returned from active service in South Africa. Among those present were: Colonel Squire, Surgeon-Major V. Matthews, and Captain L. Way, R.A.M.C., the adjutant; Surgeon-Captains H. W. Dodd, Harper, Gage Brown, Sharpe, Miles, and Warwick; Surgeon-Lieutenants Waggett, Turner, and Collier; Captain and Quartermaster Bennett; Lieutenants and Quartermasters Purcell and Heckstall Smith, and about 200 non-commissioned officers and men. Among the guests were Colonel Sir Thomas Gallwey, K.C.M.G., C.B., R A.M.C, principal medical officer of the Home District, Colonel Monier Williams, principal medical officer of the New South Wales force, Major Wilson, R.A.M.C., Captain Ward, R.A.M.C., Major Stonham of the Imperial Yeomanry Field Hospital, Surgeon-Captain T. H. Openshaw, Civil Surgeon Green, Mr. Oliver Williams, Lieutenant Collins, Civil Surgeon A. Evans, and Surgeon-Lieutenant Granville, civil surgeon, R A.M.C Most of the men who have returned from South Africa were present. Colonel Squire proposed the toast, "Our comrades who are or have been on active service in South Africa," and mentioned that in the 16 years of its existence the Volunteer Medical Staff Corps had already on three occasions offered volunteers for active service. In the Soudan campaign of 1885 a large number of members offered themselves, but he himself was the only one accepted. In the Soudan campaign of 1898 the corps offered a bearer company, and when in the summer 1899 war with the Transvaal seemed inevitable, a similar offer was made. To this the usual answer was received, that it was not contemplated to make any use of volunteers; but up to the present time over 80 officers, non-commissioned officers, and men had gone to South Africa. This formed over one-fifth of the strength of the London companies and about 30 were still serving, and to them he wished a speedy and safe return. Three would never return. Of these, one, Private Williams, went out in the Imperial Yeomanry and was killed in action near Kroonstad, and Private Walker and Private Stevens met with an equally honourable death from disease. It was hoped to record their devotion to the country by some fitting memorial. To those who had returned he offered a hearty welcome after the hardships which they had undergone. They had done all that was expected of them and more and the corps was proud of them. Surgeon-Captain Openshaw, replied, and expressed his sense of the good work which the men had done Major Matthews proposed the toast of "The Visitors" and Colonel Sir Thomas Gallwey, who was principal medical officer of Buller's force in Natal, replied, and spoke very highly of the work done by the Volunteer Medical Staff Corps in all the different forces in which they had served. Major Stonham urged that the field hospital and the bearer company should always be under the same command Colonel Monier Williams had nothing but praise for the way in which the medical arrangements had been carried out under very severe circumstances. He mentioned that there were many medical men and medical students serving as combatants, and that he had had to obtain permission to call upon some of them to undertake medical duties, in which they had proved very successful.

THE WAR IN SOUTH AFRICA.

We are mainly indebted to Lord Kitchener's laconic and business-like telegrams for all we know about the progress of military operations in South Africa. Although it cannot be said that any large or striking success is recorded as having been achieved in any particular telegram—the enemy being too wily and adroit to give the chance of it by making a stand in any force—Boer losses are steadily going on and the amount of them in the aggregate when several telegrams are taken into account is very considerable. The Boer losses in food, forage, ammunition, horses, and stock cannot, it is certain, go on for ever, however long and disappointing this method of reaching the end may be. There is no doubt that both sides—British and

Boers—are heartily sick of the war: the former in making fatiguing marches in pursuit of an enemy they fail to catch and the latter in making efforts to escape and in frequent trekking. In the sick returns enteric fever still occupies a prominent place. Plague happily seems to be making no serious progress. We lately called attention to the introduction and successful working of a field-force-canteen system in the army of South Africa. We may call our readers' attention to a very interesting communication published in the *Spectator* of May 18th from Mr. J. W. Fortescue under the head of "Coöperation for the Army." This communication and the editorial note thereon are well worthy of being read at the present time when so much is being said and written about army reform

THE CARE OF THE WOUNDED IN NAVAL WARFARE.

In an article occupying two-thirds of the *Archives de Médecine Navale* for March Dr. Léo reviews the important question of the removal and accommodation of wounded men in naval warfare. "One may say without exaggeration," says Dr. Léo, "that as regards regulation and installation the arrangements for succouring the wounded during combats at sea have not advanced a single step for the last 30 years." Dr. Léo supports his accusation with exhaustive references to official publications and documents, as well as by quotations from several authoritative writers whose descriptions of the existing arrangements for the wounded in particular instances could not be more condemnatory. The problem to be solved is a complex one, bristling with difficulties in every direction. Unless the necessary space is provided in the original plans when the framework of a vessel is under construction it is hopeless to expect that on completion she will possess adequate medical and surgical accommodation. The reservation *ab initio* of sufficient room for hospital wards and annexes and of sufficiently spacious avenues leading down to them is absolutely essential, but, as Dr. Léo observes, it is of equal importance that the installations which have obtained sanction should not be modified subsequently out of all recognition during the armament and equipment of the vessel. In practice, unfortunately, this is what usually takes place with the most disastrous consequences.

THE HEALTH OF WEST AFRICA.

A letter from Mr. Chamberlain, the Colonial Secretary, was read by the President of the African Trade Section of the Liverpool Chamber of Commerce at their annual meeting which deserves to be recorded in connexion with the efforts which are being made by the Chamber, in conjunction with the Liverpool School of Tropical Medicine, to check the ravages of malaria on the West Coast of Africa. Mr. Chamberlain expressed his gratification at having learned that, by the generosity of a Glasgow citizen, the Liverpool School of Tropical Medicine had been able to arrange that Major Ronald Ross should proceed to West Africa. He understood that Major Ross proposed to select for the experiment of trying whether the extermination of the anopheles mosquito can be effected a town either in Sierra Leone or on the Gold Coast, and the governors of those colonies had been requested to afford him all the assistance in their power. The Colonial Secretary further stated that he had suggested to the Secretary of State for War that the officers of the Royal Army Medical Corps in Sierra Leone would probably be able to give material help if the experiment should be made in Freetown. The President mentioned that the Glasgow citizen referred to in Mr. Chamberlain's letter, who desired to remain anonymous, had given a donation of £1000.

THE SYRACUSA CONVALESCENT HOME, TORQUAY, FOR WOUNDED AND INVALIDED SOLDIERS AND SAILORS.

The half-yearly meeting of the subscribers of this home was held on May 6th under the presidency of Colonel Stovell. Mr. J. Quick reported that during the past six months 66 fresh cases had been admitted, principally patients recovering from enteric fever, only eight being convalescent from wounds. 192 cases have been admitted since the opening of the institution, and the general conduct of the men had been very good. The expenditure for the half-year amounted to £475, and there was a favourable balance. Colonel Stovell stated that the difficulties with which the committee have had to contend relative to the treating of the men to drink have been overcome by the adoption of a new rule prohibiting the patients entering public-houses. Any infringement of this rule renders the men liable to instant dismissal. Surgeon-General G. J. H. Evatt of Devonport had agreed with the committee that the rule was essential.

DEATHS IN THE SERVICES.

Deputy Inspector-General Daniel Finucane, R.N., on May 15th, at Southsea, aged 72 years. He entered the Navy in 1851, and retired with the rank of Deputy Inspector-General of Hospitals and Fleets in 1883.

Brigade Surgeon William Beale Wallis, A.M.D., retired, at Colchester, on May 6th, aged 71 years. He joined the Army in 1853, became Surgeon in 1862, Surgeon-Major in 1873, and retired eight years later.

Deputy Surgeon-General William Johnstone Fyffe, A.M.D., retired, at his residence at Clifton, near Bristol, on May 17th, aged 75 years. He entered the Army as Surgeon in 1847, and retired in 1871.

Captain H. A. L. Howell, R.A.M.C., is the recipient of the Parkes Memorial Prize and the bronze medal for the best essay on military hygiene

Correspondence.

"Audi alteram partem."

"LOCAL v. GENERAL ANÆSTHESIA IN CERTAIN CASES OF ABDOMINAL SURGERY."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of May 11th, p. 1322, Mr. T. H. Morse makes the, to my mind, somewhat extraordinary statement that "the causes of shock are especially twofold—viz., the anæsthetic and the extent of injury to the nerve structures produced by the operation." With regard, first of all, to the extent of the nerve injury produced by the surgeon as a shock-determining factor, I should have thought that the nature of this injury and the seat of it were of far greater import in determining the amount of shock than the extent of it. Compare, for example, the amount of shock that usually accompanies an amputation through the shoulder-joint for, say, a sarcoma of the head of the humerus, with that which may be expected to result from the operation of nephrectomy for a similar growth of the kidney. In the first case the injury to the great nerve trunks of the brachial plexus is infinitely greater in extent than is the nerve injury in the second case; yet it is well known to both surgeons and anæsthetists that there is hardly any major operation that is attended with so much danger to life from shock as is that for the removal of a diseased kidney.

With regard to the effect of the anæsthetic *per se* as being one of the "especial twofold factors" in the production of shock I can only say that in my experience—and I believe my opinion would be supported by the majority of anæsthetists—such a statement cannot be said to rest upon facts of clinical observation I am unable to ante-date my memory to the pre-anæsthetic days, but the experience gained by administering various general anæsthetics to many hundreds of patients entitles me to express my conviction that in the large majority of cases the effect of the anæsthetic is undoubtedly to diminish rather than to increase the shock which is necessarily attendant upon all surgical operations of any degree of magnitude. I have on many occasions started to administer a general anæsthetic (gas and ether, chloroform, or a mixture of chloroform and ether) to a patient with a feeble, irregular, and frequent pulse, and have found that after complete anæsthesia has been produced for a short time the pulse becomes stronger, more regular, and less frequent and that this improved condition of the circulation has been maintained throughout the operation.

The cases referred to by Mr. Morse as being those in which a general anæsthetic is especially contra-indicated are cases of "acute peritonitis, internal hæmorrhage, and intestinal obstruction," and in support of this contention he records the notes of five cases that he has operated upon under local anæsthesia. In four out of the five cases he says "the operation was followed by no shock," or "no shock was caused"; and yet in one of these (Case 2) the hand was introduced into the abdomen "for the purpose of removing blood-clots, of which the whole cavity was full." A proceeding entailing such manual manipulation of all the abdominal organs as this would necessitate could hardly, one would think, be accomplished by the surgeon without *some* shock resulting, though if he were particularly dexterous this might be reduced to the least degree. It would be interesting to know what Mr. Morse exactly understands by "shock" and the symptoms he relies upon for gauging its intensity.

In contrast to these five cases operated on under local anæsthesia Mr. Morse records the case of a woman, aged 42 years (Case 6), to whom ether was administered for the relief of incomplete intestinal obstruction, in whom the stomach contained "fæcal matter" at the time of the operation. This patient died from suffocation caused by sucking vomited matter into her lungs whilst under the anæsthetic. Of such cases Mr. Morse truly says. "When ether or chloroform are given it is very likely that while the patient is unconscious some of the fæcal matter will be regurgitated from the stomach and sucked into the air-passages," and on this account principally, he says, "all of these are cases for operation with a local anæsthetic."

I would like to point out to Mr. Morse a very obvious and simple proceeding which entirely removes this danger. It is a precautionary measure that I have adopted for several years past and that is doubtless also frequently practised by other anæsthetists in certain cases of intestinal obstruction requiring an anæsthetic for an operation. It is to pass an ordinary flexible stomach-tube into the stomach before commencing the anæsthetic and so withdraw the contents, and, if necessary, wash out the stomach as well. If on account of the patient resenting it there is difficulty in doing this it can be safely done as soon as he is under the anæsthetic and before the operation is commenced. Only during the past week I was called upon to administer a general anæsthetic—chloroform I selected—to a woman in almost identically the same condition as the patient above referred to by Mr. Morse, and had I not resorted to the precaution I have above mentioned (which in this case resulted in the removal of about a pint of fluid from the stomach) the patient would have been exposed in a similar way to the risk of being drowned in her own vomit. As it was, she took the anæsthetic without causing the slightest alarm to either the surgeon or myself.

The introduction of reliable and safe local anæsthetics is undoubtedly a great boon to the operating surgeon, though whether it is more advisable to use one of these than one of the well-recognised general anæsthetics in the class of cases Mr. Morse specifies it is not my object in this letter to discuss. I will only say that I cannot recall a single case of this nature where I have thought that the shock of the operation has been materially increased by the administration of a general anæsthetic, when this has been given by a skilled expert; nor have I so far, for reasons of safety, had to refuse to administer a general anæsthetic to such a case when the surgeon has considered it in the interests of his patient to perform an abdominal section.

I am, Sirs, yours faithfully,

Norwich, May 13th, 1901. SYDNEY H LONG.

"LEGISLATION AGAINST NATIONAL INTEMPERANCE."

To the Editors of THE LANCET.

SIRS,—In his letter in THE LANCET of May 11th, p. 1365, Dr. Archdall Reid expresses some surprise that I should have failed to grasp his meaning on this important question of alcohol and heredity[1] I think that I may well be forgiven the apparent dulness of my perception centre when one considers that Dr. Reid takes up a position diametrically opposed to all temperance reformers, and further, that he takes his stand on premisses which, when fully examined into, he himself acknowledges to be untenable. What are these? In his earlier writings he started with the contention, "that the craving for alcohol, like sexual love, is an instinct not an acquired habit." And upon this he has built his own peculiar logical system. By-and-bye he came to recognise that his foundation was unsound and he altered it, but notwithstanding this change of foundation his structure remains the same. Dr. Reid found out that he must broaden his foundation, or rather that he must have two foundations. He calls these "factors" and he employs the terms "inborn capacity" and "acquired factor." To give his own words (1) "This capacity for enjoying alcohol is comparable to the inborn capacity for enjoying sugar or salt, or tobacco, or sexual indulgence, or so forth; (2) the second necessary factor in an inebriate's crave, the acquired factor, is the memory of the delights conferred by former acts of drinking."[2] The second factor I pass over because we are all more or less agreed as to its truth. It is his first factor which I debate and a little reflection will convince most people of its fallacy and yet it is upon this false foundation that Dr. Reid builds his house Let one only think of the comparison of an inborn capacity for enjoying sexual indulgence, sugar, and salt, with that of alcohol and tobacco. Why not add opium and arsenic? The various points compared are not parallel. Sexual indulgence, along with the tastes for sugar and salt, are essentials, tobacco and alcohol are not essentials. Sexual indulgence is necessary for the propagation of the race, sugar and salt are essentials of our life, but tobacco and alcohol are not essentials and the taste for them is entirely an acquired habit. An infant takes to sugar and salt as it takes to its mother's milk, but I never yet heard of an infant taking to tobacco or alcohol. Dr. Reid has apparently been a better boy than some of us. I am certain that he never smoked his father's black pipe, for if he did he would never have written about the inborn capacity for enjoying tobacco

So much for the theoretical part of Dr. Reid's views. His views as to its application appear to my mind quite as fallacious. "We must either permit alcoholic selection to run its level course or we must assist it by artificial selection and so prevent much of the misery by weeding out the obviously unfit either by forbidding marriage to drunken individuals or in the married by preventing the procreation of children by separating the parents or such other means as science may devise."

As a practical Christian people *we dare not allow alcoholic* selection to run its level course. If we did it would mean that in our religious and in *our social systems* there was such a deep moral blot as would bring about the destruction of our race. The advice is cold and callous and we cannot follow it, for as a people we believe that by encouragement and by making it easy to do right and difficult to do wrong we can wean men and women from evil courses of life of all kinds. We may advise against, but we cannot forbid, marriage in adults. That would mean an encroachment on the liberty of the subject which no Anglo-Saxon will tolerate. As to preventing the procreation of children by separating the parents it is pleasing to say that this is the only portion of Dr. Reid's scheme which bears scrutiny. Where both parents are drunken this may be advisable and something of this kind may be accomplished in the future. As to the other means which science may devise for preventing the procreation of children, one knows of no other means unless it be the French scheme which is as disgusting a subject as human beings can deal with and, as Sir Douglas Maclagan said, people who practised it had lost all sense of self-respect. Dr. Reid has modified his theory once and hence there is hope for him. Let us trust that he will live entirely to change his views, theoretical and practical. I am presently engaged in studying the subject of the distribution of alcoholic beverages among various peoples and hope shortly to publish my results when I shall give precise references to authorities.

I am, Sirs, yours faithfully,

Leeds, May 14th, 1901. GORDON SHARP.

To the Editors of THE LANCET.

SIRS,—The correspondence on the temperance question is one of absorbing interest to medical men. The lay public naturally look to our profession for guidance in this matter and it therefore behoves us to be very sure of our ground before we give our approval to any scheme of temperance reform. A commendable effort is now being made to get to the root of the matter and apparently there are two schools of thought giving publicity to their views in your columns. The one, ably represented by Dr. T. S. Clouston, holds that we must look for success to some form of prohibitive legislation; the other, of which Dr. Archdall Reid is the exponent, asserts that all prohibitive temperance legislation has failed in the past and is assuredly foredoomed to failure in the future for the reason that the alcoholic diathesis is hereditary.

---

[1] THE LANCET, April 27th, 1901, p. 1233

[2] Brit. Med. Jour., Sept. 16th, 1899

As stated by Dr. Walter Kidd the controversy really hinges on the question as to whether acquired characters can or cannot be transmitted. Assertions that they can be have been made and denied, what we must have, however, is proof; man, in the course of his life history, acquires thousands and thousands of characteristics, is there any proof that he has ever transmitted one of these acquirements to his offspring? Obviously the onus of proof lies with those who make the assertion; it is, of course, impossible for those who dispute it to prove a universal negative. It seems to me that if the transmission of acquired characters can be proved (and in the wide range of the whole animal kingdom, if such a transmission exists, surely there must be thousands of examples) then Dr. Reid's theory falls to the ground. If, on the other hand, no proof can be adduced, then we, as scientific men, must be very chary of supporting any scheme of reform which ignores a fundamental principle in the causation of drunkenness.

May I add, and I am open to correction, that it appears that some of your correspondents rather confuse Dr. Reid's views with those of Weissmann and other biologists; but if I am right Dr. Reid has repudiated Weissmannism properly so-called, and only follows him so far as to agree that acquired characters are not transmissible. Then, again, after Dr. Reid's destructive criticism[3] of Dr. Berry Haycraft's Milroy Lectures it is hardly correct to assume, as has been done by Dr. Walter Kidd, that the views of these two gentlemen are identical. Trusting you will allow the importance of temperance reform and the hope that this discussion may lead to its being based on sound scientific principles, to be my excuse for troubling you with this letter,

I am, Sirs, yours faithfully,

Portsmouth, May 14th, 1901. A. Mearns Fraser.

To the Editors of The Lancet.

Sirs,—Dr. Laing Gordon in his letter in The Lancet of May 18th, p. 1427, has somewhat obscured the issue raised in my letter of May 11th, p. 1365. It is not the manner in which inborn characters are transmitted, nor the view held by Dr. Archdall Reid of Weissmannism as a great body of doctrine, which is material, but the fact that an integral part of that system is adjudged by high authorities to be "not proven." It is the assertion that only inborn characters are transmitted [illegible] nged and this is vital to D [illegible]

Blackheath, May 20th, 1901. Walter Kidd.

MOTOR-CARS FOR MEDICAL MEN.

To the Editors of The Lancet.

Sirs,—Being one of the first medical men in England to adopt the automobile as a means of locomotion and being written to frequently for my opinion and experience of this means of getting about it has struck me that a few words of advice might help those medical men who contemplate changing the horse for the motor. The principal points for intended purchasers to keep in view are: First, every maker will assure you that his car is the best on the market and never breaks down; and, secondly, any maker of repute will give a trial run. Before buying try several makes and compare experiences, but do not decide unless you have had at least 25 miles' run, as many of the smaller cars seem excellent when only tried over a few miles of good road, but in spite of what the makers say to the contrary they often fail on a steep hill.

The three types of car on the market are electric, steam, and petrol.

1. Electric may be the cars of the future, but in their present state they are not suitable for medical men. The cost of the up-keep is immense owing to the short life of the accumulators, the distance run on one charge is too short for an average medical man's round, and they take a long time re charging.

2. The steam-car. The best known at present is the "Locomobile"; it is a neat-looking machine [illegible] but for a medical man it i [illegible] makers may say: (1) it is too light and must have pneumatic tyres, and the liability to puncture is a fatal obstacle, as the medical man cannot choose his road, and a puncture when on an urgent call would be just as likely to happen as at any other time; (2) it takes too long to get up steam; and (3) it uses so much petrol that it is more than four times as expensive per mile as the Benz, Mors, or Daimler. The constant anxiety of watching the water-gauge lest the water in the boiler gets too low and a tube burn out is a nuisance to a medical man; then the water-tank only holds enough for about from 12 to 15 miles. It would do for short distances on good roads, but not for the rough use of medical work.

3. Benz, Mors, and Daimler cars are driven by explosions of petrol mixed with air; in the Benz and Mors ignition is by electric spark only—in the Daimler by electric or lamp. The Benz and Mors are belt-driven and in wet weather the belts are liable to slip Several of my friends have tried the Benz, but have given them up for other makes. They are light and, judging from my friends' experiences, this has been an advantage, as they have had to push. In addition to the belt trouble with Mors cars they are fitted with pneumatic tyres, and if these are replaced by solid tyres the jolting on the ordinary road breaks the spokes. They are much too complicated for anyone but an engineer or someone with a love of engineering to take as a substitute for horses.

The Daimler is, to my mind, the best car on the market at present. The principle of the engine has proved most successful, and is that of the Panhard in France and Canstatt Daimler in Germany. I have driven my present car for about a year and a half and have never once failed to keep an appointment nor have I ever had to be towed home, though I have towed home Benz cars, Mors, and Locomobiles belonging to friends and acquaintances After a year and four months' running I drove to Coventry from Windsor to have the car overhauled and varnished. It did the journey without having to stop except once to fill the petrol tank from my extra supply can When tested at the works the engine gave five and three-quarter B.H.P., and this at the end of over a year's wear during which it had run about 6000 miles. My present car cost about £450 and is a mail phaeton with moveable hood and is the type of car I would advise those who can afford to pay so much for a machine to buy.

I believe that the car most likely to suit medical men will be a car of which I saw drawings, &c., at Coventry. It will, I am informed, cost little over £250 and drive by means of a live axle. The amount of repairs required on my car for one year and three months' wear did not amount to £10. I have since had a new water-tank and top speed gear wheel. I have spent a certain amount on improvements such as wheel-steering and compression plates on pistons to increase horse-power, but these things were not necessities and are fitted to all new cars now.

My advice is, Get a good car from a good maker, leave experimental cars to men who have time to make experiments, and when you have a car take a personal interest in it. I might mention that my experience has been of nearly three years' duration and I have had much less worry than when I drove horses.—I am, Sirs, yours faithfully,

Windsor, May 20th, 1901. H. E. Bruce Porter.

To the Editors of The Lancet.

Sirs,—In the discussion now going on in your columns *re* motor-cars perhaps my experience may be of interest. I have had a motor now nearly 12 months. I had difficulties and mishaps at first, but these were chiefly due to want of knowledge regarding the working of the machinery, and any man must expect this until he gets to thoroughly understand his car. My car now, after a year's running, is going better than ever it did; I now have very little difficulty and can rely upon it. It was made by the Yorkshire Motor Car Company of Hipperholme. It is a petrol car with tube ignition and has a double-cylinder engine. Hence it vibrates less and makes less noise than most petrol cars. It will mount any hill which a horse and trap can mount. The tyres are pneumatics. I have so far had only three punctures and the tyres, although I have ridden over the roughest roads, are now, after nearly 12 months' wear, practically as good as new. Steam cars have some advantages over petrol cars, but they have also a number of disadvantages, and until they are much more perfect I think a petrol car is to be preferred, and if I were going to buy another petrol car I should select one similar to that which I now possess. I may add that I used this car in practice with success before I removed here to take up the duties as medical officer of health of Halifax.

JAMES T. NEECH.
Halifax, May 20th, 1901.

"THE MEDICAL PROFESSION AND THE FRIENDLY SOCIETIES."

To the Editors of THE LANCET.

SIRS,—No attempt seems to have been made so far in this correspondence to settle what may be considered fair remuneration for club work. Both Mr. Brabrook and "A Colliery Surgeon"—the former in THE LANCET of April 27th, p 1232, and the latter in THE LANCET of May 11th, p. 1366—ask the question, the former rightly leaving the answer to the profession, the latter declaring himself satisfied with a payment of about *4s.* per annum. I believe few men think that club practice pays. The beginner takes it *faute de mieux* and keeps it, either because the better does not come or because the resignation of his clubs would throw them into the hands of a rival practitioner or serve to introduce an opponent. Club work is "slumped" with private work, and this "slumping" is, I contend, the main reason why the inquiry whether the former is really remunerative has not been pressed. Everybody admits that it should pay, and Mr. Brabrook places it in this respect between the attendance on the very poor and the comparatively rich.

This question of what is a proper club payment can very obviously be approached from two directions. 1. Let us imagine a medical practitioner who does club work only all his life, never having or hoping to have a single private patient. What sum should he receive? What are his wants? He must have a house, servants, and all the apparatus of medical practice. He should be able to live in fairly easy circumstances. Financially, he should be at liberty to marry and it should not be accounted a misfortune if he has two or three children. It is not too much to ask that he should be able to bring up one son to his own profession and to educate his other children in a corresponding manner. He must have occasional holidays and neither he nor his family is exempt from illness and its attendant expenses. Inasmuch as the clubs will not pension him when he is too old or too infirm to work longer for them he should be able to put away something every year for his old age. I do not think this can be done on less than £800 a year. Now £800 a year means at the ordinary rate a club *clientèle* of 4000—a number which seems unmanageable by one man. Perhaps someone with large experience of club work will tell us how many members a medical man could attend giving all his time and doing his work well. If the sum mentioned above be accepted a simple division will show what each club member should pay a year. 2. What sum does a club medical officer actually receive for each attendance? Will "A Colliery Surgeon" and others in club practice take the trouble to divide the year's club receipts by the year's attendances (presuming they are all entered) and tell us what the quotient is? I remember hearing of one provident institution in London where this sum worked out to 2½*d.*

My own feeling is that *4s.* a year is a ridiculously inadequate payment, and I would suggest that it should be made into a retaining fee in consideration of which the medical man should attend club patients for very small payments to be made out of a special medical fund raised by separate contribution from all the members. The surplus of this fund might be divided at the end of each year as is done with the funds of slate clubs. Of course, this is a vain suggestion as long as medical men profess themselves satisfied with the ordinary terms.

I am, Sirs, yours faithfully,
C. SCOTT WATSON.
Wonersh, May 13th, 1901.

"HÆMORRHAGIC TYPHOID FEVER."

To the Editors of THE LANCET.

SIRS,—In a note on hæmorrhagic typhoid fever in THE LANCET of April 20th, p. 1156, you call attention and attach importance to the history of alcoholism in the two cases of that rare affection referred to, and express an opinion as to the probability of this factor acting as a contributory cause. From this view there can be no radical dissent, but in view of the infrequency with which the hæmorrhagic diathesis is manifested in the course of typhoid fever, even in alcoholic subjects, this influence, it seems to me, must be of most subordinate significance. It appears far more likely that the widespread and profuse hæmorrhages are to be attributed to changes in the blood or vessels, or both, induced by the infective or toxic activity, or both, of the typhoid bacilli, or as a less likely possibility by some secondary infection or intoxication. The two cases in question were reported from the Philadelphia (City) Hospital where a history of alcoholic excess is the rule and that of venereal infection is common, but even here cases similar in character to those reported are, as elsewhere, most exceptional.

I am, Sirs, yours faithfully,
AUGUSTUS A. ESHNER.
Philadelphia, May 4th, 1901.

"COINCIDENT TYPHOID AND MALARIAL INFECTION."

To the Editors of THE LANCET.

SIRS,—In a leading article in THE LANCET of May 18th, p. 1412, on this subject you comment on the term "typho-malarial" in connexion with some recent observations by Dr. J. P. Lyon of Buffalo, and if you will allow me I would like to draw attention to some observations of my own as summed up in the Alexander Prize Essay for 1881—Enteric Fever as Illustrated by Army Data at Home and Abroad. The composite word was coined by Dr. Woodward during the civil war in America to meet cases where "the attack was of a mixed character from the entrance simultaneously of both exciting agencies in the system" and by the date mentioned the name had crept into the army medical returns, but the curious feature observable was that while from the typically malarial countries no clear recognition of this hybrid disease was discernible in the statistics it figured decidedly in the returns from other stations where malarial fever was not common and where the remark appended was not uncommon that the cases of paroxysmal fever had "originated elsewhere." After pointing out that the difference in causation between the paroxysmal fevers and enteric fever was deducible even from the statistics I noted that "the onset of febrile disturbance in the tropics may simulate ague," and that "ague and enteric fever may be often combined in the sense that enteric fever may occur in a malaria-impregnated person," and this latter virus by being roused into activity may modify the febrile disturbance and other symptoms, and came to the opinion that while one or two cases recorded by Dr. Massy from Newera Ellia in Ceylon seemed to support the view of a simultaneous entry of the two agencies in the system at the same time, yet that the majority of the asserted hybrid cases—based on clinical data and especially temperature variations to be found at the onset, mid-period, and decline of the fever—could be explained by the results of the old malarial taint or by deviations from the supposed typical temperature chart common in enteric fever in aliens in tropical countries and also observable in the same disease at home irrespective of malarial taint. The inference I drew was much the same as that contained in the summary at the end of your article, that the term "typho-malarial" to express a distinct disease was untenable, and subsequent experience has but confirmed the conclusion that if this asserted hybrid is to be recognised in nomenclature at all its proper status is as a variety of enteric fever dependent on the prior existence of the malarial parasite in the body.

I am, Sirs, yours faithfully,
FRANCIS H. WELCH, F R.C.S. ENG.,
Surgeon-Colonel (retired) Medical Staff
Brandram road, Lee, S.E., May 20th, 1901.

PROTRACTED GESTATION.

To the Editors of THE LANCET.

SIRS,—This morning, with some difficulty, I delivered a primipara of a male child (weight, 9 pounds 10 ounces), in every respect well developed. The last day of the mother's last period was July 2nd, 1900—that is, 320 days from the birth of the child this morning. I have made every and all possible inquiries respecting the aforesaid dates and can thus absolutely confirm them. The monthly nurse was engaged from

April 1st I think that this should be recorded, and thus beg you to do so

I am, Sirs, yours truly,
G H HAMES, F.R C S Eng

Hertford street, Mayfair, W, May 18th, 1901.

"THE CASE OF AN ELECTION."

To the Editors of THE LANCET

SIRS,—I am much astonished that no reply has been forthcoming from the authorities of the Samaritan Hospital to Dr Shaw Mackenzie's letter in THE LANCET of April 6th, p 1044 The case is even stronger than Dr Shaw-Mackenzie puts it I find that Dr Shaw Mackenzie's name appears in the list of the staff of the Samaritan Hospital in Churchill's Medical Directory for 1901 I have made inquiry into the matter and I have satisfied myself that the list came to Messrs Churchill from the hospital in the usual way It seems an extraordinary state of things that a man can be elected to a post and then removed from his duties without a word of explanation or regret No "legal opinion" can possibly justify such treatment

I am, Sirs, yours faithfully,
JAMES B BALL

Upper Wimpole-street W, May 21st, 1901

THE RECENT MEETING OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON

A CORRECTION

To the Editors of THE LANCET

SIRS —I desire to point out that in your report of the meeting of the Comitia of the Royal College of Physicians of London in THE LANCET of May 18th, p 1410 the name of Dr James Taylor has been wrongly mentioned as the seconder of Dr Norman Moore's motion instead of my own As a member of the Committee of Management I seconded the adoption of their report

I am, Sirs, yours faithfully,
FREDERICK TAYLOR

May 20th 1901

"ROYAL ORTHOPÆDIC HOSPITAL"

To the Editors of THE LANCET.

SIRS,—Mr Marks has not answered the letters of the senior house surgeon of the Royal Orthopædic Hospital and of myself—in THE LANCET of April 13th, p 1106, and March 9th, p 739 respectively—setting forth reasons against the sale of the site He assumed the reins of power in that institution by means of votes created for the purpose of defeating the scheme of purchase of the former committee He holds power by the same following of votes Under these circumstances he refuses to give reasons for suddenly changing his views and insisting upon the sale of the hospital The objections to the sale of this valuable freehold, almost the only asset of the hospital, remain unchanged We who have resisted the proposal to sell have increased the sums offered from £28 000 to over £37 000 But we do not wish to sell and believe that removal to a leasehold in an out-of the way quarter would be disastrous to the financial and social future of this old established institution Why should Mr Marks maintain an obstinate silence on a matter of vital importance to a public charity? Why should he write a private letter to the Editors of THE LANCET in answer to the comments contained in the article of April 6th last, p 1025? What has he to say to the editors of a medical journal that he cannot say to its readers? I inclose my card

I am, Sirs your faithfully,
A GOVERNOR OF THE HOSPITAL

May 19th, 1901

A DETAIL IN THE COSTUME OF MAYORS

To the Editors of THE LANCET

SIRS —May I ask if any of your readers can inform me if the mayors of Oxford and Cambridge, should they happen to be members of the university wear their academical hood over the official robe Is it usual or correct for provincial mayors w o are also doctors of medicine to wear their hoods over their mayor's robes on official occasions?

I am, Sirs, your faithfully,
HISTORICUS

May 20th, 1901

DOMESTIC DRAINAGE IN PARIS

A HOUSEHOLDERS' SYNDICATE TO RESIST SANITARY REFORM

(FROM OUR SPECIAL CORRESPONDENT)

DOMESTIC sanitation is making but slow progress in Paris The sanitary authorities hoped, and thought, that the drainage of the great majority of Paris houses would be terminated by the time that the Universal Exhibition opened its doors in 1900 They did not count, however, on the tenacity, ingenuity, and avarice of the owners of house property The reforms projected, it is true, were not of a nature to injure the interests of householders They represented, on the contrary, what was and has been proved to be in the best interests of property owners, but they entailed a preliminary outlay, and the certainty of an immediate loss, however great might be the prospective gain, has proved a serious obstacle Originally the sewers of Paris were not intended to receive domestic drainage They had their outfalls into the Seine, and the river is too small and too far inland to receive the drainage of the houses Slop water was allowed to flow into the sewers, but the closets all drained into cesspools or into portable tubs or pails In the course of time, however, and after endeavours extending over many years, the town has acquired sufficient land at Gennevilliers, Achères, Triel, and Méry to receive the whole sewage of Paris, some 180 000 000 cubic metres per annum and throw it on to the soil Being thus utilised for agriculture and purified there was no longer any objection to draining the closets into the sewers for the crude sewage was henceforth not allowed to flow into the river The completion of these works was inaugurated on July 8th, 1899 and they have already been described in THE LANCET [1] Simultaneously with this great work for the disposal of the sewage more sewers were built in the town and many of the old sewers were repaired or relaid Then pressure was brought to bear upon householders so that they should substitute for their cesspools or their pails properly flushed water-closets draining direct into the sewers By the end of the year 1890 there were only 1835 houses in Paris which were thus drained and the mortality that year was equal to 24 1 per 1000 of the population In 1893 there were 4298 houses with water-closets and the mortality was 21 7 per 1000 In 1896 there were 9460 houses draining direct into the sewers and the mortality was equal to 19 per 1000 inhabitants for the entire town Of course, there were other causes that contributed to this reduction in the death rate, but, nevertheless, there has been a notable reduction in the death rate accompanying the improvement in domestic drainage

At the present moment there are in all 78 000 houses in Paris and of this number nearly 24 000 houses now possess water closets and drain direct into the sewers For the remaining 54 000 houses there are still in existence 47 913 cesspools, 21,813 *tinettes filtrantes* (metallic pails which while retaining the solid matter allow the liquids to flow to the sewer) and 11 909 wooden tubs or pails which retain both solids and liquids The cesspools are supposed to be emptied once in the year and the pails removed once a week or oftener When the cesspool or the pail systems are employed there is no water in the closets and no syphon traps can be applied A pan can only be cleaned with a brush and by pouring a little water on it from a hand jug If much water is used the proprietors soon find this out and complain to their tenants, for they object to the cost of frequently emptying the cesspool Under these conditions the soil pipe is always foul and there is nothing to prevent the air from the soil-pipe and the cesspool below entering the dwelling rooms of the house With the *tinette* the position is better, a larger quantity of water may be used since it can escape from the *tinette* into the sewer The law of July 10th, 1894, sanctioned the raising of a loan by the town of Paris at 4 per cent interest for the amount of £4 700 000 This was to be devoted to purchasing land sufficient to receive 200 000,000 cubic metres of sewage per annum, allowing for a maximum of 40,000 cubic metres of sewage per hectare per annum Then there was the cost of pumps and of main

---

115, and July 15th, 1899, p. 186.

sewers to carry the sewage to this land, the cost of building new sewers in the town, of repairing old sewers, and the cost of completing and increasing the distribution of the water-supply, so that each house might have water enough to flush the closets and apply the new system of drainage destined to replace the cesspools and the pails. The second article of the law imposed on householders the obligation of draining all new buildings direct into the sewer, and all old buildings were to be altered within the space of three years. The town of Paris was to finish the entire scheme within five years, and the public works were completed, as has been already stated, in July, 1899. It is with the private owners of the houses that the difficulty and delay have arisen. The great majority were quite content to let matters rest as they were. So long as tenants were willing to rent their houses they did not feel disposed to incur the expense of reconstructing the closets and soil-pipes.

There was in existence a society called the Syndicate of Proprietors which was supposed to defend and represent the interests of the proprietors of the houses that are let out in flats, as is the case with nearly all the houses in Paris. But there was not much for this society to do, and most of the proprietors did not give themselves the trouble to join it. Now, however, the syndicate saw its opportunity. Circulars were issued to all the proprietors of houses urging them to join the syndicate, which would provide legal advice, and reminding them that by union they would obtain the force necessary to resist the imposition of new burdens. In a comparatively short time some 9000 proprietors joined the syndicate, and as each member paid a subscription of 20 francs per annum this meant an income of some £7200. With this the syndicate was able to open an office, employ a paid secretary, clerks, and solicitors, and even to issue a periodical which is their official organ. Many individual proprietors who if left to themselves would not have had the courage to resist official pressure felt bold and daring now that they had a powerful syndicate at their backs. The syndicate on its side had to justify its existence by the display of great activity. They therefore organised in a systematic manner a campaign on behalf of the proprietors and against the authorities. Two lines of action were adopted—the legal and the theoretical. Some engineers who did not theoretically approve of the scheme of drainage adopted by the authorities of the town were selected. The syndicate then succeeded in obtaining the necessary funds to appoint a committee of technicians who were sent to Berlin and other towns to report on the drainage of these places with a view to collect material for the condemnation of the Paris scheme. This committee went so far as to pretend that at Berlin the separate system had been adopted. Yet the only ground for such an assertion is that the sewers of Berlin are much smaller than those of Paris; therefore the storm overflows come sooner into action than they would do for the larger sewers of Paris. The sewage farms of Berlin consequently receive a smaller proportion of the storm-waters than the sewage-farms of Paris, but the sewage is not separated, both rain-water and sewage proper going to the sewers. Whatever dissatisfaction existed with the Paris scheme of drainage was thus fostered and encouraged and the controversies that had prevailed for many years before the actual scheme was finally adopted were thus revived and reopened. At the same time the action of the authorities was openly challenged before the courts of law.

A great blunder had been committed of which the Syndicate of Proprietors took due advantage. The law of 1894, sanctioning the sewage scheme, did not give any details as to how the domestic drainage in connexion with the scheme was to be carried out. Therefore this was settled by a decree issued by the Prefect of the Seine on Dec. 24th, 1897. Article 4 of this decree stipulated that proprietors or householders must submit their plans of domestic drainage to the administration, and that such plan should not be carried out unless it was approved and sanctioned. The municipality had established a sanitary laboratory where all closets, flushing tanks, and other sanitary contrivances were tested, and the idea was to prevent the employment of cheap, shoddy, and unsatisfactory appliances. But it was maintained that in taking these prudent and useful measures the Prefect of the Seine had exceeded his legal powers and the Council of State to which appeal was made gave a verdict against the Prefect. It was therefore necessary to withdraw the decrees and the regulations on this question, and issue a new decree simply stating that closets must be sufficiently flushed and the soil-pipe disconnected from the sewer.

Of course, all these efforts of the Syndicate of Proprietors will not prevent the drainage scheme from being carried out in the long run, but they have been successful in delaying its application. In some instances, also, the houses will not be as well drained as if the original regulations of the Prefect of the Seine had been enforced. Inferior apparatus may be employed, because the plans cannot be so strictly controlled by the municipal authorities. The fact, also, that these legal questions were pending provided a sufficient excuse for many proprietors to delay the application of the new system of drainage to their houses. Thus the new drainage scheme was not fully carried out in time for the arrival of the many visitors expected at the Universal Exhibition. Indeed, at the present moment, out of every 102 houses in Paris only 24 drain direct into the sewers. Thus, rather more than three-quarters of the houses of Paris are still in an unsatisfactory and insalubrious condition so far as their system of domestic drainage is concerned.

On the other hand, the fact that nearly a quarter of the houses in Paris are now in a fairly satisfactory condition constitutes a very effective object lesson Though the majority of the inhabitants still live in unwholesome houses, nearly everyone has some friend or acquaintance who lives in a house that is properly drained. Everybody, therefore, has opportunities of comparing the old system with the new; and the advantages of the latter are so obvious that persons who are removing naturally seek out an apartment in a house which is properly drained. Therefore the proprietors who have applied the new system let their apartments with great facility, whereas the apartments that still drain into cesspools or pails are apt to remain tenantless for a considerable time. Thus the force of competition is showing itself as effective as the law in breaking down the resistance of the proprietors. The law is a lame instrument to employ for the following reasons. When it is recognised that the sewer in a street is in a proper condition the proprietors of the houses on either side are notified that they must abolish their cesspools or pails, provide flush tanks to their closets, and drain direct into the sewer. Three years' delay is accorded to carry out this work. At the end of the three years the proprietor may present himself to the authorities with some doleful tale of financial loss or difficulties and appeal for a further delay. But the granting of such delay pledges the proprietor to carry out the alterations when the time has expired. If, on the other hand, it is determined to enforce the law, then a sworn agent must proceed to the house and draw up an indictment (*procès verbal*). Thereupon, the proprietor is summoned before a police-magistrate and fined from one to five francs and 16 francs costs. This is a trifle, but the proprietor is also ordered to carry out the works. If he is determined to resist he refuses to do so. Thereupon a further order is issued authorising the municipality to undertake the work and charge the cost to the proprietor. Here the difficulties begin; for the proprietor will carefully watch every detail of the work done, and if any damage is produced, such as a crack in a wall, through the digging of a trench to place a drain-pipe, then he at once sues the municipality for damage done to his property. Endless litigation results, so that it is not very practical for the municipality to push matters to this extreme. Now, also, that some of the proprietors who were most violent and energetic in resisting the new scheme of drainage are beginning to realise its advantages and are voluntarily coming round and putting their houses into proper order, the municipality is tempted to let matters take their own course.

That a considerable improvement has even now been effected is shown not merely by the figures given of the number of houses draining into the sewers, but also by the fact that it has been possible to abolish the celebrated depôt at Bondy. The cesspools of Paris are emptied by contractors who convert the contents into guano or otherwise utilise them. But they were not able to deal with the whole of the soil and the town had to establish a depôt at Bondy, where for one franc per cubic metre they took what proportion of the contents of the cesspools the contractors were unable to treat. At Bondy a contractor working for the municipality extracted ammonia from this night-soil but he was very embarrassed to know what to do with the liquid residue. Though not bearing on the question at issue, it is worth noting, while alluding to the Bondy depôt, that a very interesting experiment was made with this liquid. M. Masson, director of the municipal sanitary department, suggested that a sandy field close at hand should be utilised. Collecting drain-pipes were sunk in this field to a depth of three or four feet and the liquid residue of the contents of the cesspools, from which the ammonia had been extracted, was thrown on to this field. The water collected by the drain pipes below came out looking, if anything, blacker and more foul than before. The contractor was for giving up the experiment, but just at that time M. Bechmann, chief engineer of the town of Paris, delivered a lecture describing experiments made in England on the bacteriological treatment of sewage. M. Masson was so impressed that he insisted on continuing the trial at Bondy. In time the sand in the field got so clogged with slime and bacterial organisms that it finally acted as a filter and the liquid, which at first came out quite black, was now clear and appeared to have been purified. But with the gradual abolition of cesspools in Paris due to the ever-increasing number of houses draining directly into the sewers the contractors found that they no longer had any need to apply to the municipality to help them to get rid of a portion of the night soil. Thus the enterprise at Bondy has come to a natural end and one great centre of pollution and of foulness has thus happily disappeared.

In THE LANCET of August 13th, 1892, p. 396, there was published a special article on the cholera epidemic then prevailing in Paris, with a map of the neighbourhoods in which the depôts of night soil and the manufactories of human guano were indicated. From this map it will be seen how Paris is surrounded by these depôts of filth and their accompanying unwholesome industries. This will help to show how great will be the benefit when all the cesspools are abolished and there is no longer any need for such accumulations of night-soil in the suburbs of the town. That this end should have been delayed so long is due, as explained, to an organised resistance which does not say much for the intelligence of the proprietors of the houses of Paris. Indeed, their resistance was most short-sighted. They strove to avoid the cost of putting water-closets in their houses by arguing that the separate system of drainage was the best. Undoubtedly there is much to be said in favour of the separate system, but that would not alter their position so far as domestic drainage is concerned. Whether a soil-pipe from a house leads to a sewer which only receives sewage proper or to a sewer which also receives the rain-water does not in any way alter the method of constructing and flushing the closets or of disconnecting and of ventilating the soil-pipe. But the proprietors do not seem to have really studied the question; they were content to clutch at any pretext for avoiding, or at least for postponing, the necessity of incurring some extra expense. M. le Propriétaire is not a very popular individual in the social life of Paris. While ever ready to raise the rent he shows less alacrity in carrying out any necessary repairs; and now that these proprietors, to the number of some 900, have united to resist and defer the carrying out of a law that was undoubtedly enacted for the public good they have justly brought down upon themselves more than their usual and not inconsiderable share of public opprobrium. That the abolition of pails, *tinettes*, and cesspools, and the construction of proper water closets in all the houses of Paris, will very materially help to reduce the death rate has been demonstrated over and over again by the experience of many towns. Those who resist such reforms assume a very heavy responsibility, for they may be accountable for the loss of many human lives.

Paris, May 20th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Ahmednagar and the Boer Prisoners.—The Decline of the Plague Epidemic.—The Punjab Government and Medical Fees.—The new Presidency General Hospital in Calcutta.—Encouragement to Native Sanitary Inspectors.—The Cost of Last Year's Famine.

THE question of the hour is the reputed unhealthiness of Ahmednagar as a station for the Boer prisoners. Apart from its selection from a military point of view it may be at once said that a place which is maintained for the stationing of about 1000 British troops ought to be suitable to receive a smaller number of Boers. The town stands on the plateau of the Deccan 2125 feet above the sea, and in the district there are hills rising to 8000 feet. During 1898 and 1899 enteric fever caused an increased mortality, but the insanitary conditions to which the disease was then attributed have been remedied, and it is said that the prevalence of the disease has much lessened since. For intermittent fever it compares favourably with India as a whole, and heat-stroke is distinctly less there than at most other stations. Dysentery is not so prevalent as in the adjoining presidency or at other stations in the Deccan, and in 1899 it was particularly free from cholera. The annual rainfall is about 26 inches, but in 1899 (the date of the last report) the water-supply was deficient owing to scanty rains. From a comparison of the admission rate and the death-rate for various diseases apart from enteric fever the station can be fairly considered a healthy one. The death-rate from enteric fever for 1899 was 10 8 per 1000 of the strength, and in 1898 it was 6 55 per 1000. The year 1899 was exceptional, and the station did not show the diminution in the amount of enteric fever which took place nearly all over India, although in 1898 it compared favourably with the prevalence of the disease throughout the whole dependency. The death-rate for enteric fever throughout India in 1898 was 10 17, which declined to 5 14 in the year 1899.

The returns for the past week show a further great decrease in plague mortality throughout India—the figures having dropped from 6304 in the previous week to 4093. Deaths decreased in the Bengal districts from 3258 to 1707, and in Calcutta from 389 to 215. In the Bombay presidency the deaths fell from 570 to 468, and in Bombay city from 602 to 393. In the North-West Provinces the deaths also fell from 662 to 424. The Punjab alone shows an increase—viz., from 518 to 547 deaths. 20 cases of plague, however, are reported at Patiala and the disease has broken out in Allahabad. There were 5147 cases of plague vaccine sent out from the Plague Research Laboratory, Bombay, last week. Of these, 2000 went to Gurdaspur and the Sialkot district, 1407 to Simla to the Punjab, 1000 to Karachi, and 503 to German East Africa.

The Punjab Government have interfered in the matter of charges rendered on account of medical attendance on the late Maharaja of Patiala and the ladies of the palace during 1899 and 1900. One item of the account amounts to Rs. 5250 and the Lieutenant-Governor thinks this ought to be reduced to Rs. 1750 which would equal Rs. 100 per diem for attendance, and Rs. 50 per diem for the detention of the medical attendant in the Patiala State.

The new Presidency General Hospital in Calcutta is not yet open. Up to the end of March last a sum of nearly 15 lakhs was spent upon it, but it does not appear to be the intention of the local Government to proceed much further at present. The works are practically completed for the new block for males, for the nurses' quarters, and the beginning of the infectious diseases ward. The idea of a dairy has been abandoned.

The Bengal Government propose to give three scholarships of Rs. 50 per mensem tenable for one year to passed students of the Sibpur Engineering College who undergo a course of practical training under the sanitary engineer with a view to providing trained men for service under municipalities and district boards.

In the financial year 1900–1 the expenditure on famine relief is estimated to have been £4,227,000, and special advances amounting to £947,000 were made to agriculturists.

May 4th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Medical Appointments at the Royal Infirmary.

AT the meeting of the board of the Manchester Royal Infirmary held on May 20th Mr. Joseph Collier, the senior assistant surgeon, was appointed an honorary surgeon to fill the vacancy caused by the retirement of Mr. J. Hardie. Mr. Charles Roberts and Mr. Ernest W. Floyd were appointed public to find the money. It is estimated that the total amount required will be some £250,000, towards which contributions amounting to £80,000 have already been promised. For a time the financial question seemed likely to breed mischief between the infirmary managers and the reconstruction committee. The latter contended that having selected a plan for rebuilding and collected £80 000 their functions had ceased, and that the remaining financial responsibility must rest on the shoulders of the infirmary management, a proposal to which the managers not unnaturally objected. They expressed their consent willingly to the reconstruction of the buildings on the north side with the money already collected, but they declined to permit further interference with the infirmary until the total amount of money needed for the entire reconstruction scheme was raised. To this view the reconstruction committee appear to have become converted and they have now issued an appeal for a further £170,000. Together with the request for money the committee combat at length the various criticisms to which their decisions and proposals have been subjected. The selection of the present site they defend not only on the ground of its proximity to a vast industrial population, but also because the adjoining public square, necropolis, and cathedral afford a guarantee that the site will remain an "open" one permanently, and that no other position will secure this condition unless the infirmary is removed far from the city to a place where the attendance of medical men of the highest standing cannot be commanded. They point out also that the removal of cases of severe injury or accident to a distant spot would be full of danger to the patients. The surroundings of the large London hospitals are instanced in favour of the decision and the committee further quote the opinion of Dr. J. B Russell, late medical officer of health of the city. Against the comment that the proposed plan adds 60 more beds to a site already overburdened with 600 the committee allow that in the present building some of the wards offer a greatly insufficient cubic space, but they state that the new infirmary will provide for every one of its 660 beds an amount of air-space as ample as the most advanced hospital reformer has ever alleged to be necessary, and that in every ward there will be the fullest through-and-through ventilation in addition to any system of artificial ventilation that may be adopted. The provision of the necessary bed-space is to be obtained by carrying the buildings to a height of six storeys, but this, it is urged, will be an advantage rather than otherwise, and members of the staff will, it is anticipated, compete with each other for the upper floors, an adequate service of lifts being, of course, provided. The plan, it is also explained, secures an arrangement of the buildings so that only the minimum of shadow will be cast by any one block on any other and this is advanced as one of its leading merits. In regard to their selection of a plan other than the one recommended by their professional assessor the committee explain that the plan adopted was not excluded by the assessor from any failure in regard to vital or essential particulars but chiefly from a difference of opinion in regard to the style of architecture and the general elevation, on which matters the committee think that they are quite entitled to follow their own opinion. Detailed reasons are advanced in favour of the plan adopted, the elevation of which, it is stated, will in no wise prejudice the architectural and æsthetic effect of the neighbouring cathedral. Altogether it must be admitted that the committee make out a very fair case, and it is to be hoped that any feelings of irritation which have existed will now be allowed to subside and that all interests will work harmoniously to secure the modern and thorough equipment of an institution which is one of the oldest and most valuable of the medical charities of the city. When the infirmary is rebuilt it will undoubtedly be one the largest and best hospitals in the United Kingdom. There must be a great want of tact and management somewhere if such an institution is not made fully available as a clinical school for the numerous medical students of the University. It is notorious that many of the classes at the Western Infirmary are much overcrowded, yet the wards of the Royal Infirmary find but a *scanty contingent* of students.

Glasgow University.

The executive committee appointed in January last to deal with the question of providing funds for the better equipment of the University and for meeting the demand for extended laboratory and research facilities have issued a statement describing the immediate requirements in these respects. In the medical faculty it is stated that claims more particularly arise in the departments of materia medica, forensic medicine and public health, and physiology and surgery, and it is proposed to meet these by the erection of new buildings which, together with some minor rearrangements, will cost £50,000. New buildings and apparatus needed in the science faculty are estimated to cost £45,000. The demand for increased accommodation in the faculties of arts and law will, it is anticipated, be met by the removal of the departments just enumerated into new buildings. The teaching staff ought, it is stated, to be reinforced by the foundation of professorships in civil law and in organic chemistry, and by the institution of lectureships on English language, ancient history, philosophy, and electricity. The total sum for which an appeal is made is £150,000. Towards this subscriptions amounting to £38,000 have already been privately intimated. They include a donation of £5000 from Mr. John S. Templeton and a similar sum, "ear-marked" for the physiology department, from an anonymous source per the Right Hon. J. A. Campbell, M.P. The trustees of the late Wm. Houldsworth give £2000, and Mr. Andrew Stewart, LL.D , who recently endowed a chair of Political Economy, £1500. Amongst the donors of subscriptions of £1000 are Lord Rosebery, Lord Kelvin, Sir John Stirling Maxwell, Sir Charles Tennant, Sir James Bell, Sir Charles W. Cayzer, the Right Hon. James A. Campbell, M.P., Mr. J. S Kennedy, New York, Mr. William Ker, and Mr. James Napier.

Outbreak of Small-pox at Braemar.

About a fortnight ago a fatal case of small-pox occurred in an isolated cottage at Braemar, in the Aberdeenshire Highlands. Since then there have been reported six other cases, three of which are being treated in the same cottage and the remainder (including the lady caretaker) in the local hospital, which is being enlarged to meet the emergency. The outbreak is unfortunate at the commencement of the holiday season, Braemar being a great summer and autumn health resort. All precautions as to vaccination are being taken, and a medical man and selected staff of nurses have been sent from Aberdeen specially to attend to the cases.

Elgin Infectious Diseases Hospital.

The Joint Committee of this hospital having had before them a letter from Dr. Watson, medical officer, as to the work done at the hospital during the year, have fixed the salary at £50 per annum. The charge of five guineas per head per week made for small-pox patients from Burghead was confirmed, it being stated there would be a loss rather than a profit, the total extra expense having amounted to £145, including disinfecting.

Small-pox in Aberdeen.

Professor M. Hay, medical officer of health to the city, reports that the seventh case in the present series (commencing Jan. 1st, 1901) was that of a girl employed at Broadford Works who is now nearly fit to be discharged from the City Hospital. About 300 workers in the same factory have been revaccinated and there has been no spread of the disease. The city local authority have revaccinated the following numbers :—At the Sanitary Office, 874 ; the Royal Infirmary, 1094 ; the City Hospital, 122 ; the Dispensary, 56 ; Marywell-street School, 290 ; St Clement-street School, 183 ; Woodside Police-station, 253 ; Old Aberdeen Townhouse, 139 ; Walker-road School, Torry, 192 ; Torry School, 11 ; and elsewhere, 330—total, 3544. The number of revaccinations performed privately has been still larger. The extra expense to the rates so far as is yet known is £135 13*s*. 4*d*., including £44 7*s* 1*d*. for vaccine lymph, and £91 5*s*. to medical men and others for personal services.

May 21st.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Dublin Sanitary Association.

THE council of the Dublin Sanitary Association met on May 9th and passed the following resolution :—

> That having regard to the very serious epidemic prevalence of acute pneumonia or pneumonic fever in Dublin and its vicinity, and to the proved infective or zymotic origin of this disease, the council are of opinion that the disease should take its proper place among zymotic affections in the periodical returns of the Registrar-General for Ireland.

At the previous meeting of the association a resolution was adopted calling the attention of the Local Government Board for Ireland to the eminently unsatisfactory state in which the notification of infectious diseases at present stands in the Dublin registration area and adjoining districts. It transpired that the Notification of Infectious Diseases Act had not yet been adopted in such important urban districts as Kingstown, Blackrock, and Dalkey. Moreover, there is a difference of practice as to the diseases which are notifiable; for instance, measles is not notifiable in Rathmines while it is so in Dublin and Pembroke; whooping-cough is not notifiable in Dublin or Rathmines while it is so in Pembroke. The council expressed an opinion that the time has now come for assimilating the law of notification in Ireland to that in force in England, Scotland, and Wales, where notification is now universally compulsory.

Presentation to Mr. Thomas Myles, P.R.C.S Irel.

A few intimate professional friends of Mr. Myles, President of the Royal College of Surgeons in Ireland, met some days ago at 33, Merrion-square, Dublin, for the purpose of presenting him with a carriage and an illuminated address as a mark of their appreciation and regard. Sir Charles Cameron occupied the chair and made one of his usual felicitous speeches. Sir F. Cruise, D.L., was called to the second chair, when a vote of thanks was passed to Sir Charles Cameron for kindly presiding on the pleasing occasion.

Small pox in Belfast.

At a meeting of the Belfast Board of Guardians on May 14th, one of the members stated that a woman admitted to the infirmary with small-pox had come from nursing a child in Glasgow affected with the disease, and that the bedding and furniture were allowed to be brought through the public thoroughfares of the city without let or hindrance. He referred to the matter as showing great laxity on the part of the Public Health Committee.

The Royal Victoria Hospital, Belfast, and the Medical Students.

Some recent appointments to the resident staff of the Royal Victoria Hospital have given rise to considerable adverse criticism on the part of the medical students of the school. The following are the facts. Two intern vacancies were announced to be filled up on May 11th, and for these posts there were three candidates—two old students of the school who had been resident pupils in the hospital and a third, a young medical man, the son of a well-known practitioner in Belfast, who had studied in Dublin. The appointments are made by the board of management and life governors. On the eve of the election a circular was sent, signed by the secretary of the Students' Representative Council and by the secretary of the Belfast Medical Students' Association, asking the board of management to give preference to the candidates trained in Belfast, because they have been trained in the school and have been resident pupils in the hospital. Their qualifications, the circular said, were not inferior to those of any outsider; and to appoint an outsider would cast a slur on the teaching of this school and discourage the students attending it. All three candidates were graduates in medicine; one was a first class honours man of the Royal University, the second was a pass graduate of the same institution, and the third was a pass graduate of Trinity College, Dublin. At the election the Trinity College man, whose father resides in Belfast, and who in this way had local influence among the life governors, was elected by a large majority, and the other successful man was the first-class honours man of the Royal University and one of the most distinguished men the Belfast Medical School has had for some time. As a result the students, who were most indignant, held a meeting, an account of which was published in the Belfast papers of May 18th, and passed a resolution viewing with regret the action of the staff of the Royal Victoria Hospital in connexion with the recent appointment of resident medical officers. Further, they thought that the hospital staff should have taken up a firmer position in regard to the medical qualifications of candidates. A second resolution was also passed, stating that the Belfast medical students, being dissatisfied with the treatment they received in the Royal Victoria Hospital, directed the medical secretary of the Students' Representative Council to approach the Royal College of Surgeons, Dublin, with a view to the recognition of the Union Infirmary, Belfast, as a teaching hospital.

The Irish Census Returns.

From the returns just issued the population of Ireland is now 4,456,546—a decrease of about 5·3 per cent. In three counties there is an increase—Down, Antrim, and Dublin (the presence of the two cities of Belfast and Dublin give the explanation). There is less decrease in Ulster (2·4 per cent.) than in the other four provinces. Belfast, in population, is now by far the premier city of Ireland, and relatively it has increased in numbers more than any other town in the country. Its inhabitants are now 348,876 instead of 255,950 at the last census (an increase of over 90,000). Dublin has a population now of 286,328 instead of 269,710 last census. These figures show that not only has Belfast a population exceeding that of Dublin, but that while Dublin during the past 10 years has increased by 16,618, Belfast has, during the same period, added 92,926 to its numbers. Of the other cities, Derry has increased since the last census by over 6000, Cork by over 2000, while Limerick and Waterford have diminished.

Nurses in Poor-law Hospitals.

On May 14th at Dublin Castle several boards of guardians appealed under Section 14 of 10 and 11 Victoria, ch. 90, against an order of the Local Government Board for Ireland, dated Feb. 4th, 1901. The question involved was the right of the Local Government Board for Ireland to insist upon the appointment of qualified nurses and attendants in poor-law infirmaries and hospitals.

May 21st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Lumbar Puncture in Uræmic Headache.

AT the meeting of the Société Médicale des Hôpitaux, held on May 3rd, M. Marie and M. Guillain reported an interesting case occurring in a young man suffering from albuminuria with enormous increase of the arterial pressure and complaining of very violent headache which neither analgesics nor milk diet could relieve. Lumbar puncture showed that there was considerable hypertension of the cerebro-spinal fluid, six cubic centimetres of which escaped in a jet. The headache diminished rapidly and disappeared entirely at the end of two hours. The improvement lasted for several days. It might, therefore, be asked whether certain nervous phenomena of uræmia, such as headache, transient amaurosis, &c., might not depend on hypertension of the cerebro-spinal fluid, just as in the case of cerebral tumour. If this be so, the best treatment of uræmic headache would be lumbar puncture. At the same meeting M. Legendre quoted the case of a uræmic patient suffering from headache, insomnia, and myosis, who was similarly relieved at once by lumbar puncture. At the next meeting, held on May 10th, M. Babinski added a strange case to this list of instances of relief of cerebral troubles on the reduction of the intra-spinal pressure. A patient under his care, the subject of cerebral tumour, suffered from headache which disappeared regularly for three days after the menstrual flow; menstruation, therefore, seemed here to act as a natural blood-letting, so to speak, diminishing the blood-pressure and consequently the pressure of the cerebro-spinal fluid.

The Chair of History of Medicine.

At the Faculty of Paris the chair of History of Medicine is again vacant, its occupant, M. Brissaud, having made an application to exchange to the chair of Internal Pathology which Professor Debove has given up in order to become the successor of M. Potain in the chair of Clinical Medicine. The list of candidates for the chair of History of Medicine submitted by the Faculty gives the first preference to M. Déjerine, and after him to M. Gilbert Ballet. Now M. Déjerine, an eminent neuro-pathologist, makes no secret of his intention if appointed to quit his post whenever an opportunity arises, in order to take the first chair of Internal Pathology which becomes vacant. The council of the faculty is not ignorant of this intention, but it asserts that at least M. Gilbert Ballet, the candidate second in order of preference, who will in due course be M. Déjerine's successor, has given a formal undertaking never to seek an exchange and to devote himself permanently to the chair of History of Medicine. These combinations and bargainings are criticised with much severity in medical circles. It seems, in fact, that the chair of History of Medicine is no longer the abiding place of a real specialty, and that it has become a sort of waiting-room for specialists in different branches, neuro-pathologists, physicians, and surgeons, who get themselves appointed to it by virtue of personal considerations, and who resign at once whenever they can obtain a chair of the specialty which they cultivate, the consequence being that the appointment to the latter is not made as the result of a genuine contest between specialists in the same subject It would be much better to prohibit exchange of chairs in different specialties. This chair of History of Medicine was created at the time of the foundation of the new Faculty of Medicine in 1795, and had for its first occupant Jean Goulin of Reims, a real historian, who on his death at the end of four years was succeeded by the celebrated Cabalis. The latter had no successor, the chair being suppressed. In 1869 M. Salmon of Champoteran, a councillor of State, bequeathed to the faculty a sum of 150,000 francs (£6000) for the foundation of a chair of History of Medicine. Daremberg was the first occupant and held the position for two years. His successor, Lorain, likewise died at the end of two years. Then came M. Parrot, who exchanged in 1879 to the clinical chair of Children's Diseases. On his death there was a keen competition between M. Laboulbène and M. Olivier, the latter of whom, a celebrated specialist in children's diseases, probably intended to follow the example of M. Parrot and ultimately to exchange into the chair of Children's Diseases. M. Laboulbène, however, was successful by one vote and lectured conscientiously until his death in 1898. M. Brissaud who succeeded him and has just exchanged into the chair of Internal Pathology will have lectured for exactly a year. These deplorable transactions show to what an extent in the highest medical circles in France merit may be subordinated to personal considerations.

May 20th

CANADA.

(FROM OUR OWN CORRESPONDENT.)

McGill University, Montreal.

A DECIDED change in the matriculation standard of the medical faculty of McGill University will come into effect in September, 1902 The requirements for this examination have been raised all along the line, and hereafter Greek, German, and French will be the only optional subjects at this examination In addition to this all candidates will be required to show that they are possessed of a sound practical knowledge of chemistry and a thorough acquaintance with theoretical physics, statics, and dynamics. One of the subjects of Greek, German, or French must be taken. The authorities are anxious to make the medical faculty unexcelled by any other similar faculty in the world and towards this end it is proposed still further to increase the matriculation standard in the near future, so that all candidates before matriculating in medicine will be required to show that they have taken the first-year arts course in some recognised university. Not long ago McGill University lengthened its session from six to nine months and a combined arts and medical course was established. By the present changes those students who have been in the habit of pursuing their studies while also engaged in outside employment will have to abandon the latter if they wish to continue at their medical studies.

Death of Two Toronto Physicians.

Two well-known medical men have recently died in Toronto under sad circumstances. Dr. J. Archer Watson was riding on horseback about 10 miles out of the city; a train approached, the horse backed on the track and threw its rider violently against the engine-boiler, and the rapidly running train dashed him across the road against a board fence and instantly killed him. Dr Watson was 45 years of age He graduated from Trinity Medical College in 1885 —Dr Thomas Henry Little, also of Toronto, died on the morning of April 25th from hæmorrhagic small-pox. About 10 days before his death he had been summoned to attend a young man who had recently arrived from Cleveland, Ohio, U.S.A., where small-pox was prevalent. Dr. Little developed the disease in a very virulent form and from this he subsequently died. He was 39 years of age and was a graduate in medicine of Toronto University, having been in practice in Toronto for upwards of 12 years.

The Victoria Asylum for Women.

A new asylum for women, to be called the "Victoria Asylum for Women," is fast nearing completion at the town of Cobourg, Ontario. It will be ready for the reception of patients in September. Dr. McNichol of Cobourg has been appointed to the position of superintendent and Dr. Harriet Cockburn of Toronto has been appointed assistant physician. This is the first instance in this province of governmental recognition of the claims of female medical practitioners. Since her graduation Dr. Harriet Cockburn has had considerable hospital experience, having been connected for some time with the Dakota State Asylum for the Insane, Dakota, U S.A. Dr. McNichol has retired from private practice and is at present studying in the various asylums of the province, thus familiarising himself with the work which he will have to perform.

Queen's University, Kingston.

Queen's University, Kingston, Ontario, held its annual exercises for conferring medical degrees on April 10th. On that occasion Dr. Herald, the secretary of the medical faculty, performed the ceremony of presenting the Dean Fowler Scholarship which has lately been founded by the faculty and medical graduates of this institution both in the United States and in Canada. This scholarship will commemorate the lifelong services of Dr. Fife Fowler, late professor of medicine and now honorary dean of the Faculty. Dr. Fowler went to Kingston from Edinburgh in 1854 just at the time when the medical faculty of Queen's University was being founded. He received the appointment of professor of materia medica and this he held until 1878 when he was promoted to the chair of Medicine which he continued to hold up to a year ago. He was appointed dean in 1883. Dr. Fowler, in replying to the presentation, referred to the fact that he alone remained alive at that day of all the founders of the medical faculty of Queen's University.

Small-pox in Ontario.

Only a few weeks ago it was thought that the present outbreak of small-pox in Ontario was showing signs of abating, but since that time there have been created several new centres of infection, notably one on the Indian Reserve along the Grand River in close proximity to the city of Brantford. The Ontario Board of Health recently held its quarterly meeting in Toronto and discussed the small-pox situation, when Dr. Bryce, the provincial health officer, dealt very severely with some physicians who persisted in calling the outbreak "chicken-pox" Dr. Bryce further called upon the Medical Council to discipline these physicians as they were trifling with the health of the community and obstructing and hindering the work of the provincial health officials.

Toronto Clinical Society.

The final meeting of this society for the 1900–1901 session was held on May 1st. Some interesting cases were shown and reported upon by Dr. H. A. Bruce, Dr. F. Le M. Grasett, and Dr. George A. Bingham. The annual elections were held resulting as follows:—President: Dr. J. F. W. Ross. Vice President: Dr. E E King. Treasurer: Dr. W. H. Pepler. Recording Secretary: Dr. George Elliott. Corresponding Secretary: Dr. A. A Small. Executive Committee: Dr. H. J Hamilton. Dr. H. B. Anderson, Dr. W. B. Thistle, Dr. H. A. Bruce, and Dr. G. A. Bingham.

Toronto, May 6th.

Obituary.

WILLIAM JOHNSTONE FYFFE, A.B., M.D. DUB., L.R.C S. IREL.,

DEPUTY SURGEON-GENERAL ARMY MEDICAL DEPARTMENT (RETIRED)

DR. WILLIAM JOHNSTONE FYFFE died at his residence, 2, Rodney-place, Clifton, on May 17th, in his seventy-sixth year. The deceased, who was born in the north of Ireland, graduated M.D. of Dublin University in 1847, and the same year qualified L.R C.S. Irel. He then entered the army as a surgeon and shortly afterwards was stationed at Jamaica with the 3rd West Indian Regiment. A severe epidemic of cholera occurred there during the time, and Dr. Fyffe gained much commendation by the skill and devotion which he displayed. He was afterwards attached to the 5th Dragoon Guards and served during the Crimean war, after which he was for a time assistant professor of medicine at Netley Hospital. He retired from the army with the rank of deputy surgeon-general about 30 years ago and commenced practice at Clifton. He was physician to Clifton College and on the honorary staff of the Clifton Dispensary. Dr. Fyffe was a former president of the Bath and Bristol Branch of the British Medical Association and also of the Bristol Medico-Chirurgical Society. He had retired from practice a few years ago, was held in the highest esteem by his professional *confrères* and by the residents of Bristol and Clifton. He leaves three sons and three daughters, for whom much sympathy is felt.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Eduard Golebiowski of Berlin, a recognised authority on accidental injuries—Dr. Karl Laufenauer, Professor of Nervous and Mental Diseases in Budapest.—Dr. Ferdinand Albert Heidenreich, an aged practitioner who was an enthusiastic botanist, was murdered in his own house at Tilsit by burglars.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—In May the following candidates passed in the subjects indicated:—

Surgery.—J. C Baggs (Section I), St. Thomas's and Westminster Hospitals; [illegible]

M[illegible]

[illegible] Manchester; B Goltein (Sections I. and II), Vienna; W. O Greenwood (Section II), Leeds; J. I Halstead (Section II), Manchester; S K. K. Haslam (Section II) Royal Free Hospital, C G Meade (Sections I. and II), and M. J. Ryan, St. Bartholomew's Hospital; P P. Tobit (Section I), King's College Hospital; V. F. Wall (Sections I. and II), St. Mary's Hospital; and M J. Williams, St Bartholomew's Hospital.

Forensic Medicine.—J. C Baggs, St Thomas's and Westminster Hospitals, B Goltein, Vienna; C. A Lower, Guy's Hospital and Bristol; [illegible] and M. J. Williams, St. Bartholomew's Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise Medicine, Surgery and Midwifery: P. A. Chillcott, D J Ferris, B Goltein, W. O Greenwood, J I Halstead, S K. K Haslam, J. Kemp, C G. Meade, M. J. Ryan, and V. F. Wall.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin*: Dr. H. Liepmann has been recognised as *privat-docent* of Neurology and Mental Diseases.—*Geneva*: Dr. Louis Mégevaud has been appointed to the chair of Forensic Medicine in succession to the late Professor Gosse.—*Halle*: Dr. E Kromayer, *privat-docent* of Dermatology, has been granted the title of Professor.—*Havana*: Dr. Aristides Agramonte has been appointed Professor of Bacteriology and Experimental Pathology.—*Heidelberg*: Dr. O. Simon has been recognised as *privat docent* of Surgery.—*Kieff*: Dr. Malinovski has been promoted to the Ordinary Professorship of Surgery.—*Königsberg*: Dr Garrè of Rostock has been appointed to the chair of Surgery in succession to Dr. von Eiselsberg.—*Leipsic*: Dr. Müller has been recognised as *privat-docent* of Medicine.—*Leyden*: Dr. Hansemann of Berlin has declined the Professorship of Anatomy which he was offered.—*Munich*. Dr. Haug, *privat-docent* of Otology; Dr. Mollier, *privat docent* of Anatomy; and Dr Cremer *privat docent* of Medical Physics, have been promoted to Extraordinary Professorships.—*Paris*: Dr Déjerine *agrégé*, has been appointed Professor of the History of Medicine and Surgery in succession to M. Brissaud.—*Prague* (*Bohemian University*). Dr Stanislaus Ruzicka has been recognised as *privat docent* of Hygiene, and Dr. Ladislaus Syllaba as *privat docent* of Medical Pathology and Therapeutics.

ON May 17th the Duchess of Somerset formally opened the new cottage hospital at Totnes.

DR. HENRY WARD IRVINE of Birmingham has been appointed one of His Majesty's Inspectors of Schools.

THE JACOB MEMORIAL.—The first subscription list for this memorial closes on June 20th. The honorary treasurers are Sir Charles Cameron, C.B., and Mr. L. H. Ormsby, V P.R C S. Irel., Dublin.

SOCIETY OF MEDICAL PHONOGRAPHERS.—At the society's recent shorthand examination for medical students the first prize (£5) was awarded to Mr. James M. Kirkness of Edinburgh University, and the second (£3) to Mr. Joseph P. Byrne of the Royal College of Surgeons in Ireland.

FREEMASONRY.—*Rahere Lodge, No. 2546*.—An ordinary meeting of this lodge was held at Frascati's Restaurant, Oxford-street, W., on May 14th, W. Bro. Walter Gripper, M.B. Aberd., W.M., being in the chair. Bros. Ware and Beadles were admitted to the Third Degree, while Mr. David Boyd Keown, M.R C S. Eng., L.R.C P. Lond., was initiated into Freemasonry. Grants of ten guineas each were voted for the Boys' School and the School for Girls. W Bro. Phineas S. Abraham, M.D. Dub., was elected W.M for the ensuing year, while W. Bro. Clement Godson, M D. Aberd., was re-elected treasurer. Subsequently a number of the brethren dined together.—*The Middlesex Hospital Lodge, No. 2843*.—The first regular meeting of this lodge was held at the Freemasons' Hall on May 16th, W. Bro. T G A. Burns, P.P.G.D Surrey, W.M., being in the chair The following brethren were elected as joining members: W. Bro. General the Hon. Herbert F. Eaton, Bro. A. B. Alexander, L D S. R.C S., Bro. A. R. Godrich, Bro. R. A. Young, M.D. Lond., Bro. C. Vincent Cotterell, L.D S R C S Irel., Bro. Armstrong Smith, Bro. A. F. Palmer, Bro. J. C. Cresswell, M.R C S., and Bro. E. Norton, M D. The following gentlemen were initiated into Freemasonry: Sidney Coupland, M.D. Lond., Edward A. Fardon, M.R C S Eng., John Murray, F.R.C.S. Eng., and Herbert E. Gunson, M.A.

LIVINGSTONE COLLEGE.—Livingstone College, Leyton, was opened on May 23rd by Mrs. Bruce, the elder daughter of the late traveller who gives his name to the college. Founded in 1893 for the purpose of giving a year's training in the elements of medicine and surgery to missionaries who are likely to be placed in stations far from qualified medical assistance, over 100 students have since its inception passed through the college. A pamphlet with illustrations has been issued in order to enable friends of the college to realise the conditions under which the work is being carried on in the new premises, which are intended to form a memorial in London to the memory of the late Dr. Livingstone It would have been difficult to find a more suitable building, and it has been readily adapted to its new purpose. It is hoped that the sum of £3500 which is still needed for the purchase of the property may speedily be subscribed, in order that the work of Livingstone College may be carried on without financial difficulty, and become, as it has been in the past, practically self-supporting. Full particulars concerning the college or the Livingstone Memorial Fund may be obtained from the Principal, Dr. C. F. Harford-Battersby, Livingstone College, Knott's Green, Leyton, E.

ROYAL METEOROLOGICAL SOCIETY.—The monthly meeting of this society was held on May 15th at the society's rooms, 70, Victoria-street, Westminster, S.W., Mr. W. H. Dines, B A, the President, being in the chair. Mr. Rupert T. Smith read a paper on the Periodicity of Cyclonic Winds, which was the result of a discussion of his own observations made in the neighbourhood of Birmingham during the 26 years 1874–99. The equinoxes did not appear to be very stormy periods, but from the author's tables it was shown that the greatest frequency and force of cyclonic wind occurred some two weeks before the spring equinox and some three weeks after the autumn equinox. Mr. W. Marriott gave an account of the bequest by the late Mr. G. J. Symons, F R S., to the Royal Meteorological Society. Mr. Symons (who died on March 10th last year) was the founder of the British Rainfall Organisation and was a most distinguished meteorologist. He took a great interest in the welfare of the society and he held the office of secretary for a period of 25 years and was twice elected President. By his will Mr. Symons bequeathed to the society his Cross of the Legion of Honour, the gold Albert Medal awarded to him by the Society of Arts, the testimonial album presented to him in 1879 by the Fellows of the Royal Meteorological Society, and the sum of £200, as well as such of his books, pamphlets, maps, and photographs of which there was no copy in the society's library. Mr. Marriott stated that from Mr. Symons's valuable collection he had selected for the society over 5000 books and pamphlets and about 900 photographs. A large number of the books were old and rare works, 750 bearing dates previous to 1800, while eight were as early as the fifteenth century. By this noble bequest the Royal Meteorological Society now possesses the most complete and extensive meteorological library in existence.

THE COLONIAL NURSING ASSOCIATION.—The fifth annual report for the year ending April 30th, 1901, of the executive committee of the Colonial Nursing Association has just been issued. The association, which was established in 1897 for the purpose of providing trained nurses in the Crown colonies and small English communities in foreign countries, has 67 nurses now at work, of whom 46 are employed in Government hospitals and 21 as private nurses, against a total of 56 last year, 34 being Government and 22 private nurses. The only new branch started this year was one in Costa Rica. The chief feature of the year under notice was the great increase in the staff of nurses employed by the Government on the West Coast of Africa. Eight fresh nurses were supplied to Nigeria, and Old Calabar also applied for a second nurse to supplement the one previously sent out. Two extra nurses were also selected for the hospital at Singapore, bringing the staff there up to eight Hitherto all Government appointments have been made at the request of the Colonial Office; but the Foreign Office has now made use of the organisation of the association to supply two nurses for work in Zomba, British Central Africa. In consequence of the many calls on the public purse during the past year it was felt that it would be impossible to raise the balance still required to make up the £5000 invested capital originally asked for by Mrs. Chamberlain. It is hoped that this year the remainder of this sum may be subscribed in order to set the association on a perfectly sound financial basis. In connexion with the association it has been proposed to start a sick pay fund to provide temporary financial assistance to any nurse who may become incapacitated during her connexion with the association. In order to raise the nucleus of such a fund it is proposed to hold a ball during the present year.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Habitual Drunkards.

THE Government has adopted the Bill of the Bishop of Winchester dealing with the subject of habitual drunkards and since the adoption took place the measure has been very much altered in the House of Lords In its present state the Bill makes it an offence for a convicted habitual drunkard to ask for drink in licensed premises and for the licensee to supply him, enables the husband of a woman who is an habitual drunkard to get an order equivalent to a judicial separation on the ground of cruelty, and provides a special penalty for a person found drunk while in charge of a child under seven years of age.

HOUSE OF COMMONS.

THURSDAY, MAY 16TH.

Uncertified Deaths in Inverness-shire.

Mr. JOHN DEWAR asked the Lord Advocate (1) whether the Secretary for Scotland was aware that the medical officer of health of Inverness-shire in his report recently issued called special attention to the fact that during the last 10 years there had been as many as 3957 uncertified deaths in the county; and that during last year 80 deaths were registered in the parish of Duirinish, of which 51 were uncertified by a medical attendant, that in Kilmuir 47 deaths were registered, of which 33 were uncertified, and that in South Uist, of 85 deaths registered, 57 were uncertified, and that taking the entire county, nearly 400 persons were buried during the year whose deaths had not been certified by a member of the medical profession; and (2) whether in view of these facts, the Secretary for Scotland would introduce legislation on the subject as soon as opportunity offered in order to remedy these conditions.—The LORD ADVOCATE replied that the answer to the first paragraph was in the affirmative. As he had already stated a medical certificate of death was not a necessary condition of burial in any part of Scotland, and the Government were not at present prepared to legislate on the subject.

The Manipulation of Butter.

Mr. HANBURY, in reply to questions on this subject, said that the Board of Agriculture had official knowledge of one factory in Finsbury in which butter was mixed with milk by a mechanical process and the Board were following up information supplied to them as to the existence of others. The Finsbury firm had a very large number of depôts scattered over the country and the quantity sold was presumably large. He had no power to send an inspector into such a factory, though one was admitted into the Finsbury factory on sufferance. Nor had he power to stop the sale of butter so manipulated. But the Board had been acting in concert with various local authorities to have the legality of the sale of butter so treated tested in a court of law. A conviction was recorded against the Finsbury company last Wednesday at Longton against which the defendants had given notice of appeal. There were three prosecutions pending. The whole question pointed to the necessity for fixing a standard of butter, which he hoped to be able to do without any avoidable delay.

Plague in South Africa.

Mr. CHAMBERLAIN stated in reply to a question that there was an isolated imported case of bubonic plague at Durban in May of last year, since when no further cases had been reported. The governor of St. Helena, on the recommendation of the Medical Board there, had issued an Order in Council that no person or cargo coming from ports in South Africa south of 25° south latitude should be allowed to land. The question whether this Order in Council must not be modified was under consideration and that of landing troops from Durban could not be settled until this point was decided. It appeared to him that the fears of the local authorities were somewhat exaggerated.

FRIDAY, MAY 17TH.

The Butter Question.

Mr. O'SHAUGHNESSY asked the President of the Board of Agriculture whether he would explain why the Board of Agriculture had not yet fixed the standard of water in butter, which they had been empowered to do by legislation.—Mr. HANBURY replied. The power of fixing what is somewhat inaccurately described as a standard of milk and butter was first given to the Board in January of last year. It was then decided that a committee should first inquire into the question of milk, and that committee was appointed on Jan. 29th, 1900, and reported in January of this year. We are now working in concert with the Irish Department in preparing the necessary evidence to submit to a committee dealing with butter.

Lead-Poisoning.

Sir CHARLES DILKE asked the Home Secretary whether the increase in the more serious forms of lead poisoning and decrease in the less serious shown by the return on lead-poisoning could be accounted for by any reasons which could be stated to the House in reply to a question.—Mr. RITCHIE replied: I cannot accept without qualification the hon. baronet's statement that the more serious cases of lead-poisoning have increased. The most serious cases, the fatal ones, have, as appears from the return, been reduced by one-half from 16 in 1899 to eight in 1900 In the current year up to the present only two deaths have been reported. With regard to other serious cases there was an increase among males and a decrease among females of cases of paralysis and a decrease among males and an increase among females of cases presenting brain symptoms. These are the accidental fluctuations which will always occur in dealing with small numbers. The truth seems to be that owing to the greater precautions now adopted there has been a general decrease of lead-poisoning, which in the more serious cases is qualified to some extent by the effects of conditions extending back to former years.

The Reform of the Army Medical Service.

Sir JOHN TUKE asked the Secretary of State for War whether he proposed to adopt the suggestion contained in the report of the Royal Commission appointed to consider and report upon the care and treatment of the sick and wounded during the South African campaign to appoint a departmental or other committee of experts to inquire into and report upon the steps needed to effect certain reforms in the Royal Army Medical Corps, and, if so, whether he was prepared to state the composition of such committee.—Lord STANLEY replied. The Secretary of State is preparing various proposals to submit to a committee of experts, but the composition of the committee cannot at present be stated.

MONDAY, MAY 20TH.

The Workhouse Nursing Question in Ireland.

Mr J. P. FARRELL asked the Chief Secretary to the Lord Lieutenant of Ireland would he explain on what grounds the Local Government Board had required the medical officer of Granard Union to employ a trained nurse at £1 11*s.* 6*d.* a week to nurse a baby whom he found in charge of a pauper inmate; was he aware that the nurse in question refused to live in the workhouse and took a room in the principal hotel in Granard, and could he state when such orders of the Local Government Board would be withdrawn—Mr. WYNDHAM replied. The Local Government Board did not require the medical officer to employ a nurse at the remuneration stated The master was directed by the medical officer to procure a nurse for a sick child whom he found in charge of a pauper inmate. There is no apartment available for the nurse in the workhouse and she has obtained temporary accommodation in a hotel outside. I am making further inquiry in the matter.

The Royal Army Medical Corps.

Sir JOHN TUKE asked the Secretary of State for War whether he would undertake that the report of the committee to be appointed to consider the reconstruction and organisation of the Royal Army Medical Corps would be in the hands of Members before the Army Medical Vote came up for discussion.—Mr. BRODRICK replied: It is impossible for me to give any pledge as to the time that such a committee as that proposed may think it proper to give to its duties.

Deaths from Eating Ice-cream.

Mr. T. R. DEWAR asked the President of the Local Government Board whether he was aware that at an inquest held at Hackney on May 2nd on a boy who died from ptomaine poisoning the coroner remarked that the ice-cream purchased at street barrows had caused [illegible]

[illegible] County Council some time since caused special inquiry to be made into the conditions under which ice-cream was prepared and sold and analyses of samples of this article had from time to time been made by the sanitary authorities of London. He was not, however, able to state whether recent action had been taken on the subject.

TUESDAY, MAY 21ST.

Fees of Medical Men at Irish Inquests.

Mr. FIELD asked the Chief Secretary to the Lord Lieutenant of Ireland whether he could state the Local Government Board scale of fees for medical men attending inquests, whether Dr. Synnott only [illegible]

ROYAL COMMISSION ON ARSENICAL POISONING.

MONDAY, MAY 13TH.

THE Commission held another meeting to-day in the Westminster Palace Hotel.

Mr. HUGH BAIRD, maltster, Glasgow, gave evidence as to the methods of the large maltsters in Scotland. In the case of his own business, he said that they used as fuel only anthracite coal carefully selected for its purity, and while the floor of each kiln was brushed every time that the grain was removed the beams and plates were brushed once a week or oftener if required. They had tried pneumatic malting, but it had not proved successful for brewer's malt. The difficulty they experienced with this system [illegible] the fumes passed through the malt the desired flavour in the beer could not be secured. He could not believe that hot air would have the same effect as hot fumes. Once they had used peat for fuel and the kiln was so impregnated with it that it could not be used again and was in consequence taken down. They had made no change in their methods of malting since the arsenical scare. Their malts had, however, been tested by several chemists and all the samples were found to be free from arsenic except one. The exception was reported upon by one chemist as containing [illegible] fiftieth part of a gr[illegible] chemists reported th[illegible] use l was regularly t[illegible] they had given guara[illegible] quantity of malt wi[illegible] brewers who said th[illegible] ance of the beer. In[illegible] the rule was to use l[illegible] not uncommon. To[illegible] to the fumes of th[illegible]

THE INVESTIGATIONS AT THE GOVERNMENT LABORATORY.

Mr. ROBERT GRANT HOOPER, analyst in the Government Laboratory, was the next witness, and in the course of his examination he said that the question of the presence of arsenic in beer and brewing materials first presented itself officially at the Government laboratory in the beginning of December last, when, in consequence of the discovery of arsenic in [illegible] were made to the [illegible] destruction of the co[illegible] officials with a vie[illegible] had been charged u[illegible] were then forwarded to the Government laboratory and continued to be received for some time. In all 743 samples ha[illegible] tion of the exact original gravity and a qualitative examination of the beer for arsenic would have sufficed to substantiate the claim for draw-back, but with a view of affording information to this commission it was decided to make a more detailed examination in order to obtain some precise knowledge as to the extent to which the beer had been contaminated. In all 143 quantitative determinations of the arsenic in these beers had been made. From the tables of results which he [illegible] the proportion of arsenic found varied [illegible] the 18 cases where sugar obtained from Bostock directly had not been employed, it was stated that the sugar though supplied by another firm had been manufactured by Bostock; in two instances it was found that the arsenic was due to the use of yeast or of yeast pressings from contaminated beer; in one instance the brewer stated that Bostock's sugar was in stock at the time and might have been used by accident; and in the remaining seven cases it was alleged that the arsenical contamination had been traced to the malt used. As regards the period over which the arsenical contamination extended, the oldest sample examined was brewed on May 24th, 1900. Beer at the present time was consumed very shortly after it was produced and consequently whilst there were many samples representing the November production—the date at which the contamination was detected—considerably fewer samples of beer produced at earlier dates were available. It might, however, be noted that in the one May sample [illegible] oxide per gallon was 0·12 grain; the two [illegible] and 0·19 grain respectively; the three [illegible] proportions of arsenic, and in one case [illegible] gallon; in August the average of six samples was 0·45 grain per gallon and one sample contained 0·65 grain; in September the average was slightly lower (0·33 grain), but one sample contained rather more than one grain of arsenious oxide per gallon; in the October beers the average was half a grain per gallon, and of the 21 samples eight contained more than this, two from different breweries containing as much as 1·47 and 1·28 grains per gallon respectively, though it should, perhaps, be pointed out that these were in both cases strong beers. As regards the November samples, the average was 0·42 grain of arsenious oxide per gallon, but there were seven samples in which the contamination exceeded one grain, and in one exceptional case the proportion rose to three grains per gallon. Sugar was used in varying proportions. The highest proportions of sugar to malt and grain used were 50 and 47 per cent. respectively of the total brewing materials, and in neither case did the arsenious oxide exceed 0·60 grain per gallon, but such proportions of sugar were exceptional. The lowest proportions of sugar were less than 1 per cent., and in two out of three of these the arsenic found in the beer was 0·05 grain of arsenious oxide per gallon, though in the third case it amounted to 0·22 grain per gallon. The average proportion of sugar used in the production of these beers was 8 per cent., and in the two beers showing the highest degree of contamination the proportions were 16 and 18 per cent. respectively. In many cases, however, the sugar employed was obtained from more than one firm, and no evidence had been obtained at the Government laboratory that the brewing sugars generally in use during the past year were contaminated with arsenic. Among the samples sent for examination in connexion with the arsenicated beers were three unfermented sugar solutions which were found to contain arsenic equal to 7·99, 8·14, and 2·62 grains of arsenious oxide per gallon. These were priming solutions prepared on Nov. 23rd, 28th, and 24th respectively, the first two from invert sugar and "fluid" sugar respectively, both manufactured by Bostock, and the third from equal quantities of Bostock's invert sugar and of caramel from a maker whose name could not be ascertained. Three samples of invert sugar and one of solid glucose, all stated to be of Bostock's manufacture, were also sent for examination. The invert sugars were found to contain arsenic equal to 2·04, [illegible] had since been examined. The sugars included samples taken at breweries in each of the months from June to November and the total was made up of 64 glucoses and 40 invert and priming sugars. Of these, six samples of glucose and two invert sugars were found to contain arsenic. 14 samples of glucose and six of invert sugar taken from breweries during March of the present year were all found to be free from arsenic. Of 47 samples of malt taken from breweries during the months from June to November of last year all [illegible] necessary to [illegible] of prepared [illegible] in the preparation of beers proved to be arsenicated were first examined. These samples had been received directly from the breweries and in no case was any selenium found to be present. Other arsenicated samples were examined and found to be free from this substance. Finally, a selection of the non-arsenicated sugars forwarded for examination from various parts of the country between June and March last were tested for selenium, but in these samples also no selenium could be detected. When traces of selenious acid were added to glucose or invert sugar the presence of selenium was readily demonstrated. To render the investigation still more thorough samples of imported brew-[illegible] small; it was being quantitatively determined, but it appeared not to exceed one-tenth of a grain per pound in both sugars. All samples of beer supplied under Government contracts which had been submitted for analysis since December last had been examined for arsenic; 46 samples of this class had been received and 45 of them were found to be free from arsenic, whilst one War Office sample contained about one-hundredth of a grain of arsenious oxide per gallon and was so reported.

After the examination of Mr. Hooper the Commission adjourned.

TUESDAY, MAY 21ST.

The Commission held another meeting to-day in the Westminster Palace Hotel, with Lord KELVIN in the chair.

Mr. OTTO HEHNER, Past President of the Society of Public Analysts and Chairman of the London Section of the Society of Chemical Industry, was the only witness examined, and in the course of his evidence he said that he had given considerable attention to the question of arsenic in ingredients of food and in commercial products. He had found that very minute traces of arsenic were contained in almost all samples of malt and beer which he had examined, and that at present it was practically impossible to manufacture beer quite free from arsenic. He had found minute traces of arsenic in some kinds of sugar and in molasses and varying quantities in sodium and potassium carbonates, in caustic soda, sulphurous acid, sulphites, borax, oxide of iron, &c., all articles which were used in food materials Absolute freedom from arsenic was impossible in any brewed beverage; therefore, he said, a maximum limit should be laid down along with an analytical process of determination. In the case of beer and beer ingredients a committee of the Society of Chemical Industry was now engaged in making comparisons of the various tests to detect and approximately to determine minute quantities of arsenic. Under the present system of malting, where the coal fumes came into contact with the grain, the most careful selection of the fuel would not totally exclude contamination. Most of the maltsters now were very careful in regard to their processes, but they were not so prior to the arsenical scare. In his opinion good beer could be made from good materials and yet traces of arsenic might be found in it. In these circumstances he did not see how it was possible to guarantee absolute freedom. He had received samples of what was called pure sulphuric acid, and on analysing them personally he had found traces of arsenic. He had examined two foreign beers and found them perfectly free. In the case of oxide of iron which was met with in the colouring of confectionery, the amount of arsenic was sometimes appalling. The oxide of iron gave a red or plum colour. He had never found arsenic in the samples of bloater-paste sent to him. When he found oxide of iron in the colouring of confectionery he had done what he could to stop its use He had examined golden syrup for glucose for some years past and there had been many prosecutions in this connexion, but with regard to sweets, practically none were made with glucose There had been proceedings against the sellers of jam containing glucose. Reverting to beer, Mr. Hehner said that the largest proportion of arsenic which he had found was 1·05 grains per gallon. Almost every day he found traces of arsenic in beer. Arsenic was a curious poison. He had examined a highly contaminated sample, left it, and then returned to find that all trace of the arsenic had vanished. With regard to sulphuric acid, he suggested that all of it brought into commerce should be de-arsenicated, unless notice to the contrary were given by the vendor.

The Commission will not meet again for some time for the taking of evidence.

BOOKS, ETC., RECEIVED.

Births, Marriages, and Deaths.

BIRTHS.

GERRARD—On May 3rd, at Pembroke-avenue, Hove, the wife of Major Gerrard, M B, R A.M C, of a son.

LLEWELLYN—On May 16th, at Spondon, Derby, the wife of John Llewellyn, M.R C S, of a son.

PERRY—On May 14th at the Hutt, Petone, Wellington, New Zealand, the wife of W. D Perry, L.R.C P Lond., M R C.S, of a son.

MARRIAGE.

KENDALL—IZARD—On April 30th, at All Saints' Church, Blackheath, by the Rev R. S Kendall vicar of Luxulyon, Cornwall, uncle of the bridegroom, and the Rev A Izard, rector of Slindon, Sussex, Nicholas Fletcher Kendall, M R C S Eng, L.R C P Lond., of Chiddingfold, to Kathleen Addison Izard, eldest daughter of W. Izard, Esq, of the Paragon, Blackheath

DEATHS.

BIRTWHISTLE.—May 15th, at Budleigh Salterton, William Birtwhistle, M R.C S, second son of the late Rev Canon Birtwhistle, in his 66th year.

FINUCANE.—At 26, Nightingale-road, Southsea, Hants, on the 15th of May, Daniel J Finucane, M.D, R N., Deputy Inspector-General of Hospitals and Fleets aged 73 years

FYFFE.—On May 17th, at 2, Rodney place, Clifton, William Johnstone Fyffe, M.D, Deputy Surgeon-General (retired), aged 75 years

N.B.—A fee of 5s. is charged for the insertion of Notices of Births Marriages, and Deaths

Notes, Short Comments, and Answers to Correspondents.

THE GENERAL MEDICAL COUNCIL AND UNREGISTERED DENTISTS.

To the Editors of The Lancet.

Sirs,—Will you permit an old contributor whose first article in The Lancet dates back to 1856 to enter a protest against the action of the General Medical Council in reference to unregistered dentists. Some two or three years ago I received from the Registrar of the General Medical Council a most impertinent notice telling me that if I employed an unregistered assistant I should be deemed "guilty of infamous conduct." I took no notice of this, as in New Zealand we have no assistants of any kind. But last year I received a similar notification about unregistered dentists. By this I was informed that if I administered an anæsthetic for an unregistered dentist I should be guilty of "infamous conduct in a professional respect." This was too much for my patience. The great majority of dentists here are not on the English Register, and apart from the outrageous misuse of the English language in calling the administration of an anæsthetic while another man is extracting teeth "infamous conduct," I was not going to submit to be dictated to by a council of trades unionists as to how I should carry on my practice. So I sent in my resignation and requested the Registrar to strike my name off the Register. This has been done. I was a fully qualified practitioner four years before the Act of 1858 and I am a fully-qualified practitioner now. The registration in England gave me no rights that I did not previously possess and its absence deprives me of none, but I have had the pleasure of cutting myself adrift from the very useless and incompetent corporation called the General Medical Council whose actions for years past I have looked on with contempt.

I am, Sirs, yours faithfully,

R. H. Bakewell, M.D. St. And., *ad eundem* N.Z.,
M.R.C.S. Eng., L.M., L.S.A.

Auckland, N Z., March 20th, 1901.

⁂ Dr. Bakewell does not appreciate the good work that has been done and is being done by the General Medical Council in preventing all sorts of unqualified practice. The regulation of the Council making it unprofessional for a qualified medical man to assist an unqualified dentist is one that meets with universal approval in the mother country, but the situation in many colonies is a different one.—Ed L.

BETA-EUCAINE.

To the Editors of The Lancet.

Sirs,—Could you or any of your correspondents inform me if beta eucaine is always a satisfactory local anæsthetic? I have just had occasion to use it in a case of extraction of finger nail. I injected about 30 minims of a 5 per cent. solution around the nail bed. The anæsthesia was all that could be desired, but there resulted around the tip of the finger, the day after the operation, swelling and an unhealthy blueness of the skin, and in some parts blisters were raised containing clear fluid The finger presented such an unhealthy appearance that the patient feared blood-poisoning; and is at present very uneasy as to its ultimate progress. This is the third day since the operation, and the finger still looks unhealthy and considerably swollen. The preparation of eucaine was freshly prepared by a chemist, and all instruments were sterilised immediately before use, so that I am quite satisfied that this unlooked-for result is due entirely to the eucaine. I shall be obliged if anyone can throw any light on the matter.

I am, Sirs, yours faithfully,

Evesham, May 21st, 1901. L. F. Leslie.

BENZ CARS.

To the Editors of The Lancet.

Sirs,—If your correspondent "Cornwall" in The Lancet of May 18th, p 1442, who is thinking of buying a Benz car, buys one with a Crypto hill-climbing gear attached he will be able to get up any hill he will meet with The ordinary two-speed car without this is not worth having in a hilly country. I have had a Benz car for the last two years and it has been occasionally available for use, perhaps half a dozen times during the last 12 months, on which occasions it has generally hindered a good deal more time than it has saved. And during the same period I have spent about £70 on it, and am still running up a bill Nevertheless, I have still hopes of making a good car of it and of using it this summer. But if your correspondent thinks he is going to close his stables and save money by keeping a motor he is about to buy experience. I always advise prospective purchasers, "Get your bookseller to order you twelve-months' back numbers of the *Autocar*. Read them all through, advertisements and all. Then you will have some idea of the car most likely to suit you. Have nothing to do with pneumatic tyres or a pump. Finally, having selected your car, if, when you have paid for it and got it home you set fire *to it you will* know exactly what it has cost you." Before buying a car at all I would recommend anyone to read carefully a short article in the *Field* of May 3rd on the Diesel engine. If this engine does anything approaching what is claimed for it it will revolutionise the motor industry, though it will be certain to meet with a great deal of organised and interested opposition to start with. Remember, there are many hundreds of thousands of pounds invested in the output of existing engines and components.

I am, Sirs, yours faithfully,

Stratford-on-Avon, May 18th, 1901. Harry Lupton.

To the Editors of The Lancet.

Sirs,—In answer to the inquiry of your correspondent "Cornwall" *re* Benz motor-cars I can confidently recommend them in a hilly district. With surface of main roads good and by-roads bad I have used one for the last three years with entire success and a great saving over horseflesh. They seldom, if properly cared for, want any repairs and cost about ½*d.* per mile to run. If "Cornwall" will write to me direct I shall be glad to give him the fullest particulars.

I am, Sirs, yours faithfully,

T. Prichard Roberts, L.R.C.P. Irel., &c.

St. Albans, May 20th, 1901.

To the Editors of The Lancet.

Sirs,—In answer to your correspondent "Cornwall" with regard to the above I can inform him that I have driven a Benz car for two and a half years and have done all my work in it. I have been over 15,000 miles and the upkeep has been about £40 to £50 a year. If the car is properly treated and looked after it is most reliable and quicker and cheaper than two horses. The new car is much stronger and better than the 1898 pattern. Messrs. Hewetson are most courteous and obliging, prompt in sending requisites, and moderate in price—very serious points if the parts had to be sent for from France and charged accordingly. One hears a lot of abuse of the Benz, but if a man cannot succeed with this car he could not with any. It is most simple, long-suffering, and reliable, which after all are the chief requisites for medical work Of course it must be learnt, like anything else, and the only way to learn it is to drive it. My car is practically as good as new for work, though a bit noisy from wear.

I am, Sirs, yours faithfully,

May 20th, 1901. A. Charpentier.

P.S.—With the Crypto gear it will go up any hill.

To the Editors of The Lancet.

Sirs,—Your correspondent "Cornwall," in The Lancet of May 18th, p. 1442, does not state which style of Benz car he thinks of using. The Benz firm is old established, and makes cars of three horse-power up to 50. Probably the small three horse-power car is referred to. Having owned one of these and used it in my professional work for a year, and covered some 2000 miles in that time, I may say that they are certainly reliable but rather slow cars; they are also now considered by up-to-date automobilists as old-fashioned. Their great drawback, in my opinion, is the position of the engine—behind—which renders it difficult to make necessary adjustments, &c. These cars will go up gradients of one in four slowly if the surface is good and their solid tyres would stand the rough by-roads which, as I know from experience, are in Cornwall very loose and bad in the summer. The up-keep, of course, depends on the distance run in a given time the care taken in driving, and the attention given to the car. In Cornwall repairs and renewals would frequently be needed. I would strongly advise a car of at least six horse-power with solid tyres if expense is to be considered. The three horse-power cars are very slow and unsatisfactory to drive on muddy roads in winter. I shall be pleased to give your correspondent any further information I can.

I am, Sirs, yours faithfully,

May 22nd, 1901. C. E. Abbott, M.R.C.S. Eng., &c.

Inquirens.—"Health in Africa," by Dr. D. Kerr Cross; pp. 222 (London: James Nisbet and Co, 21, Berners-street). "Management of Children in India," by Dr. Edward A. Birch; pp. 476 (London: W. Thacker and Co, Creed-lane) "Guide to Health in Africa," by Surgeon-Major Thomas Heazle Parke; pp. 175 (London: Sampson Low, Marston, and Co., Fetter-lane). "Maladies du Soldat aux Pays Chauds," pp. 181 (Paris: J. B. Baillière et Fils). "Die Krankheiten der Warmen Lander," by Dr. B. Scheube; pp. 661 (Jena: Gustav Fischer). "How to Live in Tropical Africa," by Dr. J. Murray, pp. 252 (London: George Philip and Son, 32, Fleet-street). "Guide Pratique d'Hygiène et de Médecine Coloniale," par Dr. Sadoul, pp 202 (Paris: Augustin Challamel) "Cholera in Indian Cantonments," by E H. Hankin, M.A. (Cambridge: Deighton, Bell, and Co.). During the week marked copies of the following newspapers have been received:—*Northampton Reporter, Western Press, Hants County News, Cardiff Mail, Manchester Guardian, Bristol Mercury, Express Star, Dundee Advertiser, Leeds Mercury, Bolton Chronicle, Birmingham Gazette, South Wales Daily News, Hereford Journal, Rochdale Times, Worcester Chronicle, Sanitary Record, Liverpool Daily Post* [illegible] *Yorkshire Post,* [illegible] *Herald, Times, Glossop T*[illegible]*rbyshire Times, Drapers' I*[illegible]*nt, Oban* [illegible] *Express, Church Bells, Acton Gazette Sheffield Daily Telegraph, Gloucester Journal, Preston Herald Grantham Journal, Lincolnshire Chronicle, Norwich Press, Bury Guardian, Exeter Flying Post, East Anglian Times, Dorchester Telegram, Yeovil Advertiser, Taunton Mail, Penrith Observer, Scarborough Post, Public Health Engineer, Bristol Times, Cycling, Health, Weekly Register, Midland Daily Telegraph, Huddersfield Examiner, Cigarette World, Mining Journal, Lancaster Guardian, Reading Mercury, City Press, Surrey Advertiser, Ulster Echo, Flintshire Observer, Surrey Mirror, South African Weekly News, Surrey Times, Surrey Comet, Hertfordshire Mercury, Local Government Journal, Elgin Courant, Musical News, Ayrshire Post, South Durham Mercury, Ilkeston Pioneer, Cambria Leader, &c., &c.*

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

Communications, Letters, &c., have been received from—

A.—Messrs. Armour and Co., Lond.; Messrs. Allen and Hanburys. Lond.; Apothecaries' Society of London, Secretary of; Mr. C. E. Abbott, Cheltenham.

A Clinical Lecture

ON

ACROPARÆSTHESIA, ERYTHROMELALGIA, SCLERODACTYLIA, AND OTHER ANGIO-NEUROTIC DISTURBANCES:

WITH AN ATTEMPTED CLASSIFICATION OF ANGIO-NEUROTIC DISORDERS OF THE EXTREMITIES.

Delivered at the West End Hospital for Diseases of the Nervous System, Welbeck-street, W.,

BY THOMAS D. SAVILL, M.D. LOND.,

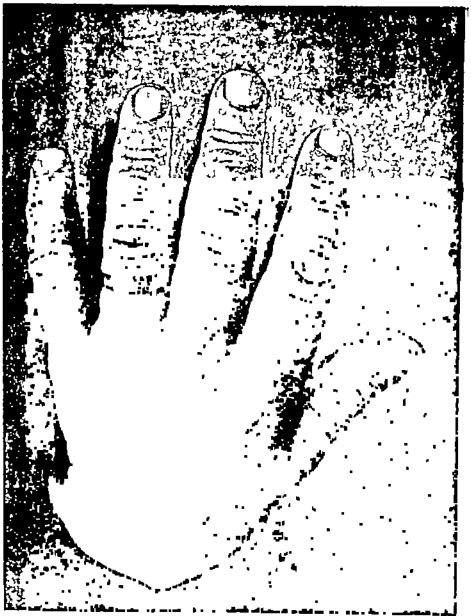
PHYSICIAN TO THE HOSPITAL.

GENTLEMEN,—"Acroparæsthesia"[1] is really a symptom. It consists of attacks of various sensory disturbances of the hands and feet, such as tingling or numbness, "pins and needles," usually without objective change, though if the patient be a close observer he may sometimes tell you that at the time of the attack the hands were unduly pale or unduly red and sometimes that there was swelling. It may occur alone, but it is quite as often associated with some other morbid condition, such as general paralysis, tabes dorsalis, or gastric disorder. "Erythromelalgia" may be regarded as a disease and the term was, I believe, first applied to it by Weir-Mitchell. The main feature consists of a painful redness with swelling or congestion of the extremities, associated with pain and the other symptoms just mentioned. "Sclerodactylia" is a term that has been applied to a localised form of scleroderma affecting the fingers and toes, and sometimes spreading to the wrists, the forearms, the ankles, and the legs.

The symptoms which these words indicate belong undoubtedly to the same category as those of Raynaud's disease. Possibly they represent an early phase, or a more chronic form, of that disorder. But the precise relation that they bear to it will be one of the questions which we shall have to investigate to-day. Acroparæsthesia and erythromelalgia are evidently very closely related, and these two conditions appear to be less uncommon than is usually believed, for during the past two years I have met with some 35 patients presenting these phenomena in a definite or marked degree. The first patient whom I intend to show you to-day is certainly one of the worst, and at the same time one of the most instructive, cases of *erythromelalgia* that I have met with.

CASE 1.—A woman, aged 52 years, first came to the out-patient department on Feb. 2nd, 1897, complaining of a painful redness and swelling of both hands. These disagreeable sensations in the hands had come on quite gradually and had lasted on and off for 12 months before I saw her. Both hands were almost equally involved, the right being a trifle the worse. The redness, swelling, and pain, which, she said, when it first started resembled "pins and needles," came on in attacks chiefly at night. Occasionally in the daytime the hands became worse, when, for instance, she let them hang down or put them into very hot or very cold water, and sometimes the attacks came on spontaneously; but at night the attacks gradually became so bad that she was unable to sleep and sometimes even to move or to get out of bed—so bad, indeed, that she had to leave off going to bed at night. A curious fact was that if she lay down in the daytime and tried to get some sleep an attack would come on. Assuming the horizontal position would make the hands worse, but if, wearied by a succession of sleepless nights, she dropped off to sleep, she was immediately awakened by the agonising pain in the hands, the wrists, and the forearms, for the redness and swelling gradually spread upwards. The hands had become almost useless owing to the stiffness and swelling, and latterly, even in between the attacks, the hands and forearms had become permanently swollen. There was never any margin to the redness; it faded off gradually to the healthy skin. The dynamometer on admission gave right 17, left 12, the normal with this instrument being about 60. This deficiency was not due to paralysis, but to stiffness and pain on movement. I show you a photograph (Fig. 1) of her hands at that time. They were both about equally crimson and congested and felt doughy, but did not pit on pressure. She could not put on gloves which she had worn six months previously. The enlargement was mainly due to congestion, because if they were held above the head for five or 10 minutes they became reduced in size and of a more natural colour. There was no history of any injury to the nerves, and there was no swelling or other abnormality to be discovered in the nerves of the extremities. The electrical reactions of the muscles and nerves of the arms were apparently normal. The patient is a married woman with three children, and she has no occupation, but her domestic duties include a great deal of washing. She gives no history of any illness, but she has suffered a good deal on and off from indigestion for some years. The change of life occurred at the age of 47 years. In early life she was much troubled with chilblains; and she has always been a "nervous" person, the slightest noise making her start and tremble, and latterly she has exhibited many of the symptoms of neurasthenia. In May, 1897, she had a curious attack of "loss of speech accompanied by twitching of the hands which lasted an hour or so." In the earlier days of her attendance at the hospital the hands were the seat of a constant, fine, rhythmical, nervous tremor, but now this is only observable when she is at all excited. Steady improvement was made under the administration of a mixture containing bromide of ammonium, and subsequently sulphate of magnesia, carbonate of magnesia, compound infusion of gentian, nux vomica, and belladonna were added. With this and the use of the constant current for seven months the attacks became milder and the hands less painful. Much of the improvement, I believe, is attributable to the galvanism. The negative pole was placed at the bottom of a jug of warm water and the positive over the nape of the neck. Each hand and arm was then inserted in the water, and as

FIG. 1.



Erythromelalgia. Reproduction of a photograph of the hand of a female patient (Case 1), aged 52 years, showing puffiness and swelling. The crimson colour cannot of course be shown. The skin was tender and had a doughy feel on pressure, but there was no pitting.

---

[1] The term "acroparæsthesia" was first suggested, I believe, by Schultze (Deutsche Zeitschrift für Nervenheilkunde, 1893).

strong a current as she could tolerate was administered for from 20 to 30 minutes three or four times a week. During the three years the patient has been attending the hospital she has very often had a mixture of gentian, alkalies, and other remedies directed to the improvement of the digestion. On one occasion after she had become worse owing to her irregular attendance I administered large doses of chloride of calcium (20 grains, gradually increased to 30 grains thrice daily after meals), and she improved rapidly under this treatment. In one way and another she has improved so much that she has ceased to attend regularly.

These are the main features of the case excepting a most interesting attack which she had in October, 1897, when she was laid up in bed at home for seven weeks. The hands became very red and this and the swelling spread rapidly up the arms, the neck, and even to the face. Purple or crimson acutely painful blotches appeared on the arms, the trunk, and the legs, and these were described by the medical man who attended her for this illness and who kindly sent me particulars (for I did not see her myself), as "exactly resembling erythema nodosum."[2] When she resumed her attendances at the hospital the hands were still too stiff and painful to hold anything and she was unable to dress herself. The pulse has generally been somewhat rapid and the radial arteries certainly seem to be a trifle thick, but there is no definite arterial lesion discoverable here or elsewhere. The slightest excitement will increase the pulse-rate immediately. The heart appears to be structurally sound, but like the patient it seems to be "nervous," if I may use the term in that sense. She has suffered a good deal from headache at different times. Indeed, this is her chief complaint at the present time—the original disease having settled down into a chronic permanent erythromelalgic condition still liable to occasional exacerbations though of less severity. It is now limited to the hands and wrists, which are still painful, stiff, and relatively useless, and worse in the winter than in the summer. There is undoubtedly a certain amount of thickening of the skin but the enlargement is chiefly due to vascular turgescence.

A uniform red swelling of the hands of the kind before you might be due to three anatomical lesions—organised infiltration, œdema which has become inflamed (cellulitis), and vascular turgescence (congestion). There is no pitting on pressure, so it cannot be simple effusion of serous fluid (œdema) such as occurs in dropsy; and it is not due to myxœdema because the patient has not the other signs of that malady. There is not any marked degree of general infiltration because, as Mr. R. E. Hanson has just demonstrated, the swelling and redness can be reduced by the simple process of holding the hands above the head. After holding the right hand up for two minutes the circumference of the fingers is reduced by one-eighth of an inch, and this is accompanied by a sensation of tingling. After being held up for 15 minutes longer the fingers undergo a further reduction of one-sixteenth of an inch. These changes are attended by numbness and tingling in the hand, and there is an obvious difference to be seen between the two hands as regards their size and feel. The left hand which has been in the patient's lap is obviously larger and the skin feels thicker.[3] It is therefore mainly an undue vascular turgescence. The fact that gravity exercises such a marked influence shows, I believe, that the vaso-motor mechanism is at fault. There is a permanent localised paralysis of the vaso-motor mechanism of the hands. Again the capillary reflex (as tested by Haig's hæmodynamometer) is delayed. It amounts to eight seconds, whereas after subduing the congestion by elevating the member it amounts to only four seconds The main lesion, therefore, in this case, is a vascular turgescence, an active or arterial hyperæmia of the hands, and it will be interesting to speculate as to the probable cause of it.

There are three possible causes of arterial hyperæmia. 1. There are certain agencies which have a weakening or paralysing effect directly on the involuntary muscular fibres in the tunica media of the arterioles. Fatigue after prolonged contraction such as that produced by prolonged exposure to cold is one instance of this and the hyperæmia after sudden removal of mechanical pressure is another, both of them being local agencies. 2. There may be paralysis of the sympathetic nerve fibres leading to loss of the continuous vaso-tonic contraction which we know is constantly present in the arterioles. Certain drugs (pilocarpine, amyl nitrite, &c.) are believed to act in this way directly on the nerve fibrils or vaso-motor centres. Reflexly, by inhibition the same effect may be produced—namely, by stimulation of a sensory nerve. 3. Excitation of the vaso-dilator nerves which physiologists have shown to exist, at any rate, in the chorda tympani. Now, I may say at once that my own view is that the case before us is partly dependent on the first of these causes, for her domestic duties involve an unusually large amount of washing. At one time her hands were always being exposed, and therefore the muscle-fibres of the arterioles becoming fatigued. This is probably why her hands were the chief seat of the mischief. But this does not explain the whole of the case, and it cannot account for that remarkable and severe attack of erythema from which she suffered in other parts of the body. The cause of this must, I believe, have been some generalised agent, such, for instance, as a toxic blood state.

Now in this case it may be remarked, in the first place, that there have never been any evidences or symptoms of any derangement either of the peripheral nerves or the central nervous system beyond a general irritability (as witnessed by the extreme nervousness and the "nervous" tremors of the hands), such as is so frequently associated with toxic blood states, as pointed out in my lectures on neurasthenia.[4] Indeed, I think we may assume that a toxic blood state is in operation in this case producing a general neurasthenic condition, and at the same time paralysis of certain of the vaso-motor nerves. An interesting feature in this case was the great increase of pain which ensued when the patient went to sleep, and this quite tallies with the explanation that I have suggested. You are aware that during sleep the tonic or continuous action of the vaso-motor centre is less, and the vessels of the surface of the body dilate; that is why we take cold so readily and why we feel the cold so much more during sleep. But this latter dilatation, added to that already existing in the hands, greatly aggravated the condition. Against the toxic origin it might be argued that the lesion was too localised for a hæmic derangement. But apart from the known proclivity which toxins have for certain localities we have seen that there existed here a determining factor in the large amount of washing and exposure.

That toxins may produce vaso-motor derangement, and that they may produce conditions very closely allied to that before us, we see in the case of ergotism where the hands are affected with an extreme vaso-constriction. Arsenic also, as seen in the recent epidemic of beer-poisoning in the north of England, may produce erythromelalgia[5] Erythematous conditions are fairly frequently met with when antitoxins are injected for the purpose of immunity. As to the nature of the toxin in vaso-motor conditions of the extremities it is purely a matter of conjecture. We have seen that this patient suffered a good deal from dyspepsia, and the imperfectly elaborated food products must necessarily form a potent source of perverted blood states. Patients with chronic dyspepsia are very apt to complain of coldness and blueness of the hands and feet, and we probably have, in the case before us, an aggravation of that condition. Indeed, it appears to me that we find in this patient's prolonged gastric derangement an explanation both of her neurasthenic symptoms and of the vaso-motor paresis which constituted the leading and most troublesome feature of the case.

CASE 2.—The patient who is coming into the room directly has suffered from Graves's disease for some years, a malady which is very frequently attended by vaso-motor symptoms and especially by some degree of *acroparæsthesia* more frequently, I believe, than is generally recognised. I am not sure that if inquiry were made the majority of these cases would not be found to have been affected in this way at some time during their illness.

---

[2] The letter which Dr. H. G. Sworn kindly wrote me is worth quoting *in extenso*. The patient "had severe pains in the arms and legs, with patches of redness (like erythema nodosum) on the flexor and extensor surfaces, also on the hands and feet The patches disappeared in about a week, leaving brown discolourations on the skin, they were succeeded by fresh patches At that time I looked upon the case as due to rheumatism and therefore treated her with salicylate of soda. The temperature varied from 99° to 101° F. Her urine deposited urates and was very acid."

[3] This experiment of holding up the hand and then measuring was suggested by my friend and pupil Mr R E Hanson. The experiment was repeated with the left hand with the same result.

[4] Clinical Lectures on Neurasthenia; Glaisher, London, 1899.

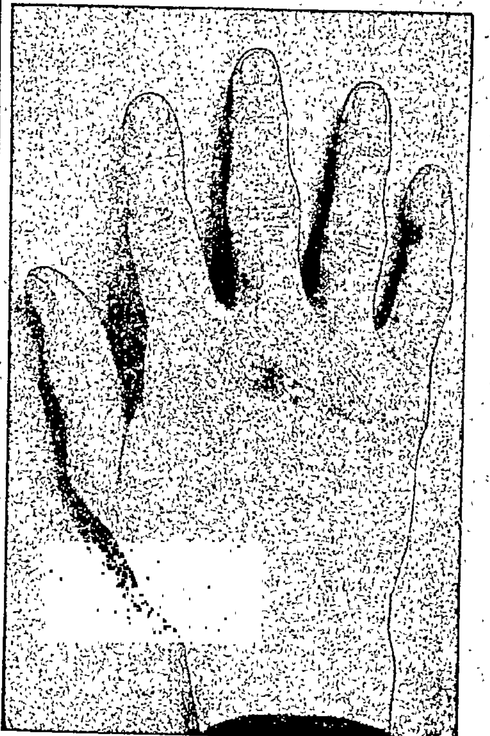
[5] Reynolds Transactions of the Royal Medical and Chirurgical Society, November, 1900.

The patient is a single woman, aged 36 years, who has had thyroid enlargement and proptosis. But the prominent symptoms in her case have always been those referable to the cardio-vascular and the central nervous systems. She is highly nervous, and she has suffered so much from agoraphobia that she has been seldom able to come to the hospital alone, though she has attended on and off for the last five years. During that time she has twice, for a period of three months, had to be placed in an asylum, so unrestrainable did her temper become. This patient presents several vaso-motor symptoms besides the rapid pulse which also probably comes into this category. She very easily flushes, and from time to time she has complained of numb sensations and "pins and needles" in the hands. This numbness is sometimes preceded by pain, the hands feeling, she says, as if they were "being crushed." During the attacks they get red and "puffy." These attacks sometimes come on spontaneously, but they may be determined by putting them in very hot or very cold water, and, like the previous case, they are worse at night when she goes to sleep and whenever she lies down, even during the daytime. She states that her mother, her maternal grandmother, and one of her sisters had their hands affected in the same way.

CASE 3. *Sclerodactylia.*—In Case 1 we had to do with attacks of painful redness and swelling of the hands, but now by a fortunate chance I am able to show you a case of precisely the opposite condition. You will remember that in Case 1 there was a dilatation of the vessels, a vascular paralysis, but in this patient we have to do with a vascular spasm, a pallor, followed by a hardening or sclerosis of the skin. The case which I am about to show you resembles Case 1 in one respect—viz., the hands are the chief seat of the disease, and the same lesion which affects the hands and forearms has appeared also on other parts of the body. It is a noteworthy fact in this case how the marked degree of sclerosis which was at one time present has almost entirely disappeared, so that I am only able to show you what remains of this.

The patient, aged 43 years, is a married woman, and the history of her illness is as follows. In 1895, at the age of 38 years, two months after a confinement, "white patches" appeared on the body. These have never disappeared and you will see on the left side of the thorax and abdomen two smooth white "ivory-like" areas, each of about the size of the hand, presenting all the features of scleroderma or, as Sir Erasmus Wilson called it, "morphœa." At one time the skin was almost as hard as gristle, but it is considerably thinner and more supple now. Shortly after these white patches appeared she began to be affected with attacks of "pins and needles" in the hands and feet. At first these attacks only came on at night and they were easily relieved by putting the hands out of bed, but by degrees they became much more severe, very painful, and gradually the condition became more or less continuous, though always paroxysmal. In addition to these sensations she noticed that the hands were becoming stiffer, owing apparently to the gradual increase in thickness of the skin. The hands, she told us, became slightly flushed just for a moment at the onset of the attacks, but did not swell, and immediately afterwards they became extremely pale and remained so. During the attacks the skin sometimes became "wringing wet with perspiration." Around the joints the skin and subcutaneous tissue gradually became much thickened so that the joints were very stiff and she could not close her hands. This thickening of the skin and subcutaneous tissue extended up the forearms for a considerable distance. This impeded the action of the muscles, which seemed matted together and bound down by the hard sclerosed skin. The feet, in this case, were similarly and equally affected, so that this unfortunate woman in the course of eight or 10 months was hardly able to walk because the ankles and the calf muscles were so stiff and "hide-bound." In November, 1896, before she came under my care, the tip of the second toe of the right foot became "cold, dead, exceedingly painful, and finally the skin at the end of the toe came off and left a sore which healed slowly and with a great deal of pain." You will see that there is a superficial scar there now. It was a year after this—in November, 1897—that I first saw her, and her hands and feet were then so stiff and painful that she could not close the former, and was hardly able to walk. The fingers were pale, thin, and tapering, owing apparently to the contraction of the skin, for the joints stood out, giving an appearance of enlargement. There was then, and there is still, you see, a certain amount of enlargement in the position of the joints owing to the thickness of the skin over them, and their movements are stiff for the same reason. But the enlargement is, I believe, more apparent than real, and due to the changes in the skin, which, by contracting down on to the shafts of the phalanges, causes the joints to stand out (Fig. 2). She was still (in November, 1897) subject to slight attacks of "pins and needles," followed by pallor and perspiration. This hardness of the skin and subcutaneous tissue extended nearly up to the elbows in the forearms and nearly up to the knees in the legs, and you will see that the skin in these situations is smooth and glossy, but it is now very little, if at all, thicker than normal. The feet are still subject to occasional attacks of pallor and sweating. As regards her previous history and family history there is nothing of importance to note. She has two healthy children. At first I put her upon iodide of potassium, but she got steadily worse, so that at one time she could hardly use her hands and arms to feed herself and she suffered greatly with pain. In July, 1898, I gave her thyroid extract (five grains) three times a day. This was subsequently supplemented by galvanism to the arms and legs three times a week for about two months, but I believe that

FIG. 2.



Sclerodactylia. Reproduction [illegible] ph showing the [illegible] and of a female [illegible]). The residual [illegible] on of the skin [illegible] skin upon the [illegible] enlargement of [illegible] naturally takes [illegible] the joints, and [illegible] in the skeleton hand. The fingers appear to be tapering from the same reason. The patient could not even at this time completely close or completely straighten the fingers as she used to do, hence the slightly curved condition of the fingers.

it was the thyroid extract (unless, of course, it was the spontaneous course of the disease) under which she made steady improvement. Week by week, month by month, the skin gradually became softer and more supple and natural and she gradually recovered the use of her hands. She is now, as you will see, apparently well, though any excessive amount of work or excess of cold or heat determines an attack of the same nature. She can walk fairly well now but the gait is still very inelegant. The patches of morphœa on the thorax are still visible, but they also have improved. They never gave her much trouble at any time.

Clinically this case appears to correspond with a somewhat rare condition which has been variously described by different authors. Thus, the "sclerodactylia," or "acro-scleroderma" of French authors, to which this case most nearly corresponds, is a condition referred to in some dermatological works[6] under the heading "scleroderma." But Kaposi[7] states that it is by French authors (Ball, Hallopeau, Dufour, Lepine) *erroneously* identified with scleroderma. Some German authors,[8] however, include it among skin diseases. The condition described by Mr. Hutchinson[9] as "acroteric scleroderma with liability to Raynaud's phenomena" probably also belongs to the same category, and a case has recently been recorded by Dr. W. P. Herringham[10] under the title "scleroderma and sclerosis of the muscles with recurrent attacks of local syncope." Dr. F. Parkes Weber[11] has recorded a case having some resemblance to this one under the title "trophic disorder of the feet — an anomalous and asymmetrical case of sclerodactylia with Raynaud's phenomena." But Dr. Weber's patient presented cyanosis (i.e., asphyxia) instead of pallor (i e., syncope) combined with dermal and sub-dermal sclerosis, and only the feet were affected. In other respects the cases had a good deal in common, though the ulcerative or gangrenous process appeared to be progressive in his case and retrocedent in mine. But, after all, the application of a name does not help us very much. The chief thing to do is to identify the pathological process which is at work. In the case which you have just seen there were two anatomical lesions: (1) recurrent attacks of vaso-constriction, and (2) scleroderma of the skin and parts beneath, limited almost, but not entirely, to the four extremities, and one of the first questions to answer is, What is the relation of these two lesions to each other? Are they products of the same cause? Is the sclerosis the result of the vascular lesion, or *vice versâ?* Unfortunately, we have not many data to go upon, but sclerosis such as this seems to me to be *almost certainly* connected with some obstruction to the return of the lymph from the parts involved. We know how intimately associated the arteries and the lymphatics are, and it seems highly probable that the real cause of the condition is a vaso-motor lesion, of a vaso constrictor type, affecting the vaso motor centres of the extremities in the spinal cord and rendering the skin of these parts unduly sensitive to external agencies. This would explain the paroxysmal and other features of the case. This would also explain the fact that the two processes (the syncopal attacks and the sclerosis) got worse and better together, allowing, of course, for the fact that the sclerosis of the tissues required longer time for absorption.

CASE 4.—In this case, again, one of "*dead-hands*," we have a vascular spasm with pallor as in the patient who has just gone out, instead of redness and swelling due to vascular dilatation. The patient is a single woman, aged 26 years, and all her life the fingers have "gone dead" whenever they have been exposed to cold. They have got much worse lately and it is for this that she comes to the hospital. In these attacks the fingers and hands assume a deadly pallor, feel quite numb and devoid of sensation, and after remaining white for some little time they resume their normal colour and then become a trifle livid. As the pallor passes off she feels a sensation of "pins and needles" and a tingling pain shoots up the arms, sometimes very severe. These attacks do not seem to be determined by anything excepting exposure to cold. They are rather more frequent at the catamenial period and are much worse in cold weather; she dare not wash in cold water. Sometimes she has had as many as a dozen attacks in a day. A whole attack may last from half an hour to two hours or so, and sometimes, she says, the hands will remain continuously white "for a long time." Warmth will generally shorten the attack. The patient came to me first in December, 1898, and all through the winter she had an average of a dozen attacks a day. As regards the capillary reflex it seems at the present time to be about normal. This case resembles an early phase of the syncopal or ischæmic form of Raynaud's disease, but the patient presents none of the other symptoms. There is no alteration in the texture of the skin of the hands or elsewhere. The heart and the arteries are normal, the arterial tension seems normal, and the pulse is normal, though it is easily increased in rate. The face is pale, but she says it has always been so. Hitherto, there has been no swelling of the hands at any time, but for the last fortnight the fingers, she says, have occasionally become a little swollen. In July, 1899, I noticed that she occasionally had a fine rhythmical tremor of the hands, and you will observe that it is present now. The association of tremor with vaso-motor lesions, both paralytic and spasmodic conditions, is in my experience a fairly frequent occurrence, but the explanation of the connexion is not very apparent. I think that they must both be the product of a common cause; and perhaps that may consist of a toxic blood condition. There is nothing of importance in this patient's personal or family history and she has never been subject to chilblains. As regards treatment, she got a little better at first under the administration of nux vomica, belladonna, and bromide of ammonium, combined with the use of the constant current, applied as in Case 1. In July, believing that the indication here was to relax the vascular spasm, I prescribed for her trinitrin in one-minim doses three times a day. It has certainly realised my anticipations and now, although the weather has been very much colder, she has greatly improved. This remedy has, I believe, done her more good than the electricity and the bromide. In order to test the efficacy of the trinitrin I have twice left it off, all the other conditions remaining the same, and each time the attacks returned.

CASE 5.—In this case (*acroparæsthesia* with other vaso-motor attacks) the *erythromelalgic* symptoms were quite transient and, compared with the other features of the case, relatively unimportant. They consisted of painful sensations in the hands attended by purple colouration. But as regards the other features, it is one of the most distressing cases of vaso-motor disorder I have met with.

The patient is a married woman, aged 38 years, who has suffered from the attacks about to be described practically ever since the age of puberty. She has sought relief at the hands of many physicians and has taken, she told me, many pounds of bromide. She is of the full-blooded type, tall and stout, with crimson cheeks and lips, and very energetic; but her life has been practically spoiled by a constant succession of three different kinds of attack, which merge, however, one into the other. First, she has been subject to "flushings" of the face and surface of the body, sometimes attended by actual swelling on the slightest excitement, several times a day. In one of these attacks I found that her neck measured three-quarters of an inch larger than normal. Secondly, she has had some very strange attacks which she aptly terms "rushes of blood to the head" attended by giddiness and "swimming in the head." Objects appear to whirl round and she is apt to fall unless she has support. On one or two occasions she did fall and injured herself. The pain in the head is very severe, the head feeling as though it "would burst" and as though it was "opening and shutting" with every beat of the pulse. The giddiness lasts from five to 10 minutes, but the bursting feeling in the head persists for an hour or so afterwards. In these seizures the surface of the body becomes cold and clammy and the pulse completely disappears from the wrist. She might have two or three of these attacks a day for a day or two, followed by an interval of a week or so; though even then she not infrequently has slighter attacks of the same nature—giddiness with a sensation of blood "rushing to the head." Thirdly, she is subject from time to time to headaches lasting for 24 hours or so, having all the characters of migraine. They generally follow a night of "horrible dreams," are relieved by emesis, and are succeeded by extreme prostration lasting for several hours. The scalp is acutely tender for some days On several occasions the headache has been attended by scintillating scotoma ("like catherine-wheels"), and one attack was succeeded by right homonymous hemiopsia lasting for two or three days. These three kinds of attacks, which have troubled this unhappy lady on and off all her life, have certain features in common. They are all specially apt to come on directly after she rises from her bed in the morning and the slighter ones may be determined at any time by suddenly assuming the erect posture or by being startled. Raising her arms, a movement that may be necessitated, for instance, by an attempt to "do her own hair," will invariably bring on the "giddy attacks" or rushes to the head. Lying down relieves them all in some degree, but if she sleeps with her head low she has very bad dreams and always has a "giddy attack" in the morning. The bowels are apt to be confined and the attacks are always worse then There is a vague history of "consumption" in the family; but apart from these distressing attacks this patient has been otherwise healthy all her life excepting for an attack of what was called "rheumatic arthritis" with which she was laid up for eight weeks in early life. The catamenia have always been very irregular. The attacks are worse at the expected period and are very severe if, as frequently happens, she misses altogether. Nothing abnormal can be discovered in the heart or viscera. She has been troubled lately with flatulent dyspepsia. She has slight hypermetropia (which has been accurately corrected by glasses), and slight granular pharyngitis As regards the latter Dr. Scanes Spicer reported, "I do not regard this as sufficient to account for her symptoms." This patient presents certain neurasthenic, or what, perhaps, some would call hysterical, symptoms. She is very "nervous" and easily startled, and she has not dared for some years to go out alone (agoraphobia). If she did horrible imaginary dreads would come over her or an attack of "giddiness." In past times many of this patient's symptoms would probably have been regarded as "hysterical," but about the reality and severity of her sufferings there is no doubt and she has vainly endeavoured for many years to get relief.

It appears to me that the chief lesion in this case is a defect of the coördinating power in the vaso-motor centre which allows the blood to collect in one part (generally the head) instead of into "the overflow reservoir"—viz, the splanchnic area. This defect, which is probably inherent or inherited, is apparently accompanied with an undue irritability of the spinal vaso motor reflex centres How to correct the former I was completely at a loss, but for the latter I ordered her a descending constant current to the spine and it was certainly attended with considerable benefit, for at the end of two weeks she reported, "The rushes have been much less frequent and lasted a much shorter time." To correct what I believed to be the causal agency of this defect attention was directed to the diet, for on inquiry I learned that she lived somewhat too well and was in the habit of passing excess of lithates in the urine. Copious libations of warm water and practically a nitrogenous diet were prescribed This produced a further amelioration, especially in the severe attacks of migraine, but unfortunately she was not able to persist in the rigorous diet which I had ordered her, and the relief was only partial.

In the next two patients the acroparæsthetic symptoms, as in the previous case, are of quite subordinate interest In the first of these two they consisted of a feeling of numbness and tingling in the hands when the other seizures to which he was subject came on. He did not notice whether the hands got pale or red We have seen that flushing or pallor may take place in many situations. If on the surface we can see the phenomenon, but if in the interior of the body it can only become manifest in other ways. The following case I believe to be due to flushing or pallor of the brain, this being due apparently not so much to vaso-motor or sympathetic disturbance as to cardiac failure combined with rigidity of the systemic vessels. Nevertheless, for reasons which will appear, I believe that the defect in other parts of the vaso-motor system played their *rôle* here also, otherwise postural alterations would not have played so important a part.[12]

CASE 6. *Acroparæsthesia accompanying various circulatory "attacks."*—A man, aged 54 years, first came to the out-patient department in October, 1898, complaining of "attacks" of various kinds which had troubled him for about seven years, at first only at somewhat rare intervals. He looks, as you will observe, considerably older than he is, and in point of fact he exemplifies the truth of the adage that "a man is as old as his arteries," for these are much impaired. He has suffered a great deal from attacks of vertigo, which came on whenever he assumed the erect posture or executed any movement which threw a strain upon the heart or circulation. The giddiness was sometimes attended by interruption of thought and sometimes he would be actually unconsciousness for a few moments, and on several occasions he fell. Latterly these attacks, commencing with giddiness, have presented all the phenomena of a severe syncope; finally, sometimes they have been followed by convulsive seizures presenting all the appearances of an epileptic fit. It has been shown by Kussmaul[13] that both anæmia and congestion of the brain may be attended by convulsions, and there is no doubt that all the various forms of attacks from which the patient has suffered—vertigo, interruptions of thought, transient loss of consciousness, syncope, and epileptiform attacks—were all due to disturbances of the circulation within the brain. The fact that the attacks could be determined by assuming the erect posture pointed very strongly in this direction. Careful investigation showed that there were no evidences of the other possible causes of the vertiginous or other attacks, and he had never had epilepsy in earlier life. There were, on the other hand, undoubted evidences of both cardiac and vascular disease, and, as we shall see, relief of the circulatory difficulties resulted in the immediate relief of the attacks. When he first came to the hospital he could not walk alone on account of the extreme giddiness from which he suffered. The breathlessness was very marked, the pulse was extremely feeble, rapid, and irregular, and of very low tension. The heart was considerably dilated both to the right and to the left, and the apex beat was situated half an inch outside the nipple line. The auscultatory signs were consistent with a dilated heart in which the valves, apart from the dilatation, were healthy. All the superficial vessels were thick, hard, and tortuous He was ordered chloroform, ether, and ammonia, and subsequently digitalis was added—nothing else—and his improvement was almost, as he expressed it, like magic. He has now been attending almost a year, the treatment all the while being directed to the heart. He came to us believing that his days were numbered, and to-day he has asked for the second time to be allowed to return to work. The heart has almost resumed its normal dimensions and the only attacks he now has are the slighter vertiginous ones, and these only occasionally. I may add that some of this patient's epileptic attacks were "latent"—e g., were unattended by convulsions—and in one of these he walked into his bedroom and began to undress without knowing what he was doing.

In this patient the acroparæsthesia was quite a subordinate feature, and I have brought him before you not so much as an example of angio-neurosis as to show you what grave effects may ensue from serious vascular and, as I hope to prove to you hereafter, angio-neurotic disorders. The case is a very instructive one, and it is somewhat unusual in that it is rare for the circulation of the brain to be so profoundly disturbed as to produce syncope, unconsciousness, and epileptiform convulsions without death speedily ensuing. I can only remember to have seen one similar case within the last 10 years It was that of a woman, aged 61 years, in whom epilepsy was supposed to have supervened for the first time at the age of 56 years, a very unusual circumstance, as you are aware. She had very strange attacks in which she did not fall but stiffened herself and leant against the nearest object quite unconscious, working her arms and jaws in a most peculiar manner. This stage was followed by stertorous respiration and a period of drowsiness. The illness had begun seven years before and as, in the male case, the attacks, which at first consisted of vertigo, gradually became more severe, were attended with unconsciousness, and finally assumed the characters I have just described. She also improved under remedies directed to the cardio-vascular system. I might add that in both of these cases a cessation of the treatment was attended with a return or exacerbation of the attacks.

Is it possible that these patients had a thrombosis or embolism of the brain—though there were no evidences of it—and that it was this lesion which rendered the brain unusually susceptible? In any case it was clearly the disturbance of the circulation which produced the epileptiform seizures. These observations help to confirm the notion that attacks of idiopathic epilepsy are due to vascular alterations in the brain, a fact which might be borne in mind in the treatment of the latter affection. I hope to return to this subject on a future occasion.

---

[12] Dr. Leonard Hill denies the existence of vaso-motor nerves in the brain. It is not a point of prime importance to our present argument but it is difficult for clinical observers to accept this statement in its entirety.

[13] Translations of the New Sydenham Society.

CASE 7. *Acroparæsthesia accompanying hemicranial sweating and flushing.*—In this case the patient is subject to attacks of tingling, numbness, and pallor of the hands from time to time, which resemble those in Case 4. The chief interest of the case, however, rests in other directions. Here we can localise the main lesion with considerable precision—viz., in the superior cervical sympathetic ganglion—and we can say that it is a paralytic or destructive lesion as distinguished from an irritative one. The patient, a woman, aged 52 years, complained of attacks of excessive perspiration preceded by a slight *flush of the left side* of the face and head. She habitually sweated more on this side of the scalp, and her hairpins got rusted on that side. When she was excited this sweating got worse and she then had a running from the left nostril. She complained also of attacks of pain in the forehead and on the top of the head, chiefly down the left side to the neck which were worse when she was in a draught or out in the cold. The attacks of pain or of sweating were sometimes ushered in by a "dragging pain" in the chest. She was very apt to get generalised flush-storms, when she went "hot all over" and perspired, then finally "went cold," when she might shiver. These attacks came on when she was "nervous." The pain in the head might also be determined by washing in cold water. These symptoms have been present on and off for three years. The wetness of the head has been her chief trouble and it was for this symptom chiefly that she applied. Here, then, we have attacks of vaso-dilatation of the left half of the head and neck, the area which is controlled by the cervical sympathetic. Let us see if there are any other symptoms of paralysis of that structure. You will observe that the left pupil is larger than the right and that it seems to get larger and smaller (more or less rhythmically) as one looks at it. There is no obvious alteration in the palpebral aperture, the ocular tension, or the prominence of the eyeball. When she is frightened or worried the pain in the head feels worse, so also are the perspiration and the running from the nose. The appetite is not good. The bowels are confined. The menopause occurred two years ago. Her present symptoms date from an illness which appears to have been influenza and with which she was laid up in bed for two or three weeks. She is subject to cold feet, and she had chilblains as a child, but there is nothing else of importance in her history. It is evidently a marked instance of a paralytic lesion of the sympathetic ganglion in the neck on the left side. There is no evidence of any growth or swelling in the neck. The case is probably connected in some way with the influenzal attack to which I have just referred. To-day is the first time that she has come to the hospital and I propose to give her ergot, bromide of ammonium, and mistura alba.

I have brought these seven patients before you because they are attending the hospital now and because their cases seem to illustrate fairly well some of the many different symptoms of angio-neurotic disorder. There are many others which I could mention, but I think that it is hardly necessary for our present purpose. They all presented acroparæsthesia or some other angio-neurotic disturbance of the extremities; and in conclusion I should like to add a few remarks, first, on the etiology of acroparæsthesia; secondly, on the most prominent symptoms which this and other vaso-motor disorders present in common; and thirdly, on the classification of these acroparæsthesic cases and the relation which they bear to Raynaud's disease.

First, as regards the etiology of acroparæsthesia. Out of 35 marked cases which I have recently observed, 29, or 82·8 per cent., were females. Excluding two children, aged four and 10 years respectively, the average age was 32·4 years. In 10 patients these conditions were secondary to other maladies, such as neurasthenia, hysteria, Graves's disease, acromegaly, and general paralysis of the insane, but the rest (25) applied for relief of the acroparæsthetic conditions.

Acroparæsthesia, erythromelalgia, and the other many and varied vaso-motor symptoms have certain features in common. 1. They are much more frequently met with in the female sex, the proportion, I find, usually being much higher than that above mentioned. I imagine that something like 90 per cent. of these cases occur in female patients. 2. Vaso-motor conditions appear to be due to some inherent and very often inherited tendency in the patient, for they recur again and again in one form or another during the life of an individual. Thus, a patient may have migraine at one time, severe flushings at another, and syncopal attacks at another, though I have generally found that there is a tendency to a recurrence of the same disorder. There are, moreover, two epochs of life which are specially prone to their development—namely, puberty and the climacteric. 3. The onset of the symptoms, whatever they may be, is always more or less sudden. 4. They are in all cases paroxysmal—i.e., they occur in the form of attacks. There is a sudden rise, when the symptoms soon reach their acme, followed by a gradual descent. In severe cases the attacks may be so frequent as to resemble a continuous malady, but close observation will detect that there are well-marked exacerbations. 5. In the great majority of the patients flushes or flush-storms occur from time to time during the patient's life; should these be absent there are generally other evidences of vaso-motor instability. 6. A great many of them—particularly of the vaso-dilator kind—are amenable to treatment by bromides, which relieve them at any rate for a time. These six features are very instructive, and many of them may be explained by the study of the physiology of involuntary muscular fibre. This and other points must be referred to a future occasion, but I wish, in conclusion, to reduce, if possible, vaso-motor conditions of the extremities to something like order and to consider what relation they present to the disease first described by Raynaud.[14] The result of my experience is embodied in the following classification and you will observe that the cases which we have seen together to-day fall naturally into one or other of the different groups.

CLINICAL CLASSIFICATION OF VASO-MOTOR DISORDERS OF THE EXTREMITIES.

A. VASO-DILATATION.—(*a*) *Early stage* (*chronic*).—Attacks of redness (congestion) and tingling, burning, &c. (*congestive acroparæsthesia*)—e.g., Case 2 and Case 5 and early stages of Case 1. (*b*) *Late stage* (*chronic*).—The symptoms are attended by swelling which gradually becomes permanent (*erythromelalgia*)—e.g., Case 1. (*c*) If the process takes an *acute* course the symptoms go on to gangrene, usually moist gangrene (*Raynaud's disease*—congestive or asphyxial type).

B. VASO-CONSTRICTION.—(*a*) *Early stage* (*chronic*).—Attacks of pallor and bloodlessness (ischæmia) attended by numbness, tingling, "pins and needles," "dead fingers," &c. (*ischæmic acroparæsthesia*)—e.g., Case 4 and Case 7. (*b*) *Late stage* (*chronic*).—The symptoms may be attended with thickening (sclerosis) of the skin and subcutaneous tissue (sclerodactylia)—e.g., Case 3. (*c*) If the process takes an *acute* course dry gangrene probably results (*Raynaud's disease*—syncopal type).

It will be seen that these varieties correspond to the different varieties and phases of Raynaud's disease, which begins in one or other of the above ways and may go on to gangrene. These cases are also probably related to the condition described by Dr. Henri Meige and others[15] under the name of "chronic hereditary atrophœdema."

Attacks of perspiration (hyperidrosis) which are sometimes met with in the extremities, probably come under the same category also, but it would not do to include these in the above classification, because although the derangement is probably seated in the sympathetic nerves, and the sweating is very generally attended by flushing, we are not sure that the sweating is not controlled by separate nerves.

These cases, gentlemen, brought together by the chances of clinical work, will give you a very fair notion of acroparæsthesia and erythromelalgia, and the relation, as it appears to me, of one to the other, and to Raynaud's disease.

We know very little about the sympathetic nervous system Laboratory experiments, which, by the way, are not wanting, have not thrown much light on the subject; and the first step in an inquiry of this kind seems to me to get a clear notion of the clinical phenomena we wish to investigate and their relation to one another. This has been my object to-day

ARTERIAL HYPERTONUS AND ARTERIO-SCLEROSIS: THEIR RELATIONS AND SIGNIFICANCE[1]

BY WILLIAM RUSSELL, M D, F R C P EDIN,
ASSISTANT PHYSICIAN, ROYAL INFIRMARY, EDINBURGH.

Introductory —I propose to ask your attention to-night, first to the various applications of the term "arterio-sclerosis"; secondly to my own observations on the condition; thirdly to a state of the arteries to which I have ventured to apply the term "hypertonus"; and fourthly to the relations of hypertonus to arterio-sclerosis "Arterio-sclerosis" is not a term of Anglo-Saxon birth, it has come to us from our brethren on the continent of Europe It is only within recent years that it has come into general use in this country, and if proof of this were wanted it is to be found in the fact that the word does not even occur in the first edition of Fagge's "Principles and Practice of Medicine," published in 1886 or in the sixth edition of Bristowe's "Treatise on the Theory and Practice of Medicine," published in 1887 If those who use the term are asked to define it a considerable variety of reply is given, and it becomes evident that a varied significance attaches to it Some mean atheroma, others mean fibrous thickening, others mean degeneration, and others mean a combination of all three conditions If there is any one characteristic which is recognised by all those who use the term that characteristic is thickening or induration of the arterial walls as tested by the condition of the radial artery Such vague and indefinite notions regarding a common condition are at least unsatisfactory, and as I have had considerable opportunities of studying the condition a brief account of my observations may be of some help in giving the condition a more definite position Before recording these observations it is, however, necessary to deal with what we may regard as the authoritative definitions and explanations of the term in question

Historical and pathological —A historical *résumé* entitled "Étude Clinique sur les Indurations des Artères," by Dr Noël Gueneau de Mussy, appeared in the *Archives Générales de Médecine* of 1872 p 129 Dr de Mussy showed that the condition is common in early and middle life and not necessarily present in old age, and he included atheroma under the term "induration" Ziegler says that "sclerosis in an artery implies the existence of local thickening of its inner coat," and proceeds then to describe atheroma He was the first to describe in detail and to discuss arterio-sclerotic atrophy of the kidney He showed that the renal arteries and their branches in aged people are very frequently the seat of sclerotic changes which may simultaneously affect the arteries of other regions also or be confined to the kidney In this condition the intima of the arteries is notably thickened and the lumen correspondingly narrowed or even obliterated, and he showed that this vascular change in the kidney gave rise to a special form of contraction of the organ which he termed "arterio-sclerotic atrophy"

All the German pathologists may be said to use the term "arterio-sclerosis" to describe atheroma, whatever else they may include under it Of all the German work, however, there can be no question that it is Thoma's which has specially influenced opinion in this country and in America To borrow a term from social life, he may be said to have "set the fashion" in the use and interpretation of the term in clinical medicine and, so far as we have been able to find, pathology has not let its voice be heard beyond the lecture room Thoma's views may be briefly summarised as follows the elasticity of the vessel wall becomes reduced in general diseases, acute and chronic infective diseases, long-continued disturbances of general nutrition, by many poisonous substances, and by functional overstraining of arteries from an increase of the heart's action. As a result the lumen dilates and the blood-stream is retarded in the widened vessel This retardation is the cause of a new formation of connective tissue in the intima of the widened artery. "The new formation of connective tissue in the intima renders the vessel wall more firm so that it appears more rigid and less yielding (arterio-sclerosis, phlebo-sclerosis, angio-sclerosis)"[2] In short, Thoma holds that the thickening of the intima is secondary to a dilatation of the vessel and consequent on slowing of the blood stream; that the thickening is to compensate for the assumed widening and to restore the equilibrium between lumen and contained blood which had been lost By this means, he maintains, the rapidity of the blood flow is re-established

If we turn to the French school we find Lancereaux in 1893 writing on "L'Endartérite ou Artério-sclérose Généralisée"[3] He defines the conditions as a proliferation of the cells of the intima which goes on to fatty degeneration due to failure of nutrition Huchard[4] mentions the fact that German authors always use the term arterio-sclerosis to signify atheroma of arteries, and he asks whether the terms are absolutely synonymous His answer is strongly in the negative He uses the term to designate a general condition of which atheroma is only one of numerous manifestations These include visceral scleroses—all dominated by a primary chronic inflammation of the small vessels described by many authors as obliterative endarteritis (or endarteriolitis) Arteritis of the small vessels, in short, he considers the anatomical characteristic of arterio-sclerosis (p 96)

Turning to English works of recent date it is not necessary to go beyond the valuable "System of Medicine" which has been edited by Dr T Clifford Allbutt Here we look for the high water mark of contemporary medicine, and in Dr F W Mott we find an exponent of the German view of arterio-sclerosis and an adherent of Thoma's views which have already been referred to He places the term "arterio-sclerosis" as the title of the section and in the introduction to the subject he says that the term "is applied rather loosely to a thickening of the vessel wall It includes the obvious naked eye change in the large arteries, named by some authors atheroma, by others, endarteritis deformans It includes also arterio capillary fibrosis, a change first described by Gull and Sutton in the walls of the small vessels, which only becomes obvious on microscopic examination" At page 320 he gives as his definition of arterio-sclerosis "a local or general thickening of the arterial wall with loss of elasticity, occasioned mainly by fibrous overgrowth of the tunica intima, secondary and proportional to weakening of the muscular and elastic elements of the media" It seems quite clear that Dr Mott includes atheroma under the term arterio sclerosis, and he follows Thoma in asserting that the primary change in atheroma is to be found in a degeneration of the tunica media and that the thickening of the tunica intima is secondary and compensatory to this He holds with Thoma that the observations made by the latter on paraffin moulds of the aorta prove this without apparently seeing that these moulds may, with equal justice, be held to prove that the atrophy of the media is secondary and compensatory to the hypertrophy of the intima It is not my purpose at present to elaborate this point, but I would indeed be surprised to find that British pathologists held this to be the order of events in atheroma For myself I may say that I have no doubt whatever that atheroma is a primary affection of the tunica intima, degeneration and destruction of the media being secondary; in fact, atheroma is so entirely a process by itself that it ought to be allowed to stand in its old position, it seems to me to be quite unnecessary to extend to it the German use of the word "arterio-sclerosis"

Passing from this question of the inclusion of atheroma in arterio-sclerosis we find that Dr Mott describes a "diffuse arterio-sclerosis" (p 329) in which the changes begin in the small arteries and capillaries, especially those of the renal cortex, brain, and heart, and are frequently associated with "nodular atheroma" of the aorta He says that "on minute examination the muscle fibres of the media show hyaline swelling, fatty degeneration, or atrophic changes so that the muscular elements are often not recognisable; this is especially the case in the small arteries of the kidney where the wall of the vessel may appear to consist of a homogeneous hyaline tissue. Sometimes the degenerated atrophied fibres of the media can be made out, but nothing of the elastic lamina, the intima being thickened and represented only by a homogeneous hyaline material with but few nuclei." The result of these widespread changes is increased resistance to flow of blood through the capillaries, hypertrophy of the left ventricle, dilatation of larger arteries from degenerative changes in muscular and elastic tissues of the media, slowing of the circulation, and compensatory proliferation of the subendothelial layer of the inner coat" (p 330). Here, again, Dr. Mott strongly commits himself to Thoma's view. In America Osler, Councilman, and others have committed themselves to Thoma's views.

From the foregoing *résumé* which, while not professing to be exhaustive, may be taken as fairly representative of authoritative views, it is seen that the term arterio sclerosis is applied to three conditions: (1) to atheroma; (2) to a generalised endarteritis; and (3) to a thickening of the intima compensatory to dilatation of vessels from weakening of their middle coat. This *résumé* could not, however, be regarded as even approximately complete without some reference to the views, expounded by men of eminence, on the relations between granular kidney and the changes in the arteries and heart which accompany granular kidney. In fact, no exposition on arterial changes could suitably ignore this side of the question.

George Johnson (1850–1873) was the first to show that thickening of the muscle coat of the arteries occurred in granular kidney, and he held that the changes in the heart and vessels were secondary to primary kidney changes. Gull and Sutton (1872–1877) propounded the view that there occurred a generalised change or disease in the vessels, to which they gave the name "arterio-capillary fibrosis." The changes in the kidney were regarded as secondary to this vessel fibrosis. Dickinson (1875) held that a growth of fibrous tissue in the kidney was the primary change and that the changes in the vessels were secondary to this. Rosenstein (1881) agreed with Johnson as to the thickening of the muscular coat of the arteries, but thought that the thickening of the intima was inflammatory. Ewald (1881) held that there were two forms of changes in the vessels connected with Bright's disease: first, that in which the kidney was affected primarily and was followed by hypertrophy of the heart and of the muscle coat of the arteries; and, second, that in which disease of the general vascular system was the starting-point of the kidney disease In this latter there was arterio-capillary fibrosis both in the kidney vessels and in the general vascular system. He thought that it was a question whether such cases should be called "Bright's disease" or not. Dreschfeld and Mahomed (1881) held practically the same view as Ewald, the latter holding in addition that there might be cardio-vascular changes without necessarily renal changes being present in all. Samuel West carried the discussion down to last year and discourses on the old theme as to whether the kidney lesion or the arterial change is the first to appear. He enters a protest against granular kidney being considered partly under vessels and partly under kidney.

Personal observations —I now ask your attention to my own observations which were conducted on a simple plan. All the cases I examined were seen by me during life. As the radial artery is the vessel which is taken as the type during life I decided to examine it after death. I also usually examined the renal artery, the coronary artery, and the kidney itself. In one case the cerebral nutrient vessels were examined by my friend Dr. Ford Robertson. In this way I have examined so far 16 cases and the results I have arrived at may be stated as follows. 1. Atheroma and arterio-sclerosis are two totally distinct clinical and pathological entities. 2. Atheroma is a localised and patchy affection of the arteries characterised by degenerative changes which have long been recognised. 3. Arterio-sclerosis is a generalised affection of the arteries and is characterised by (*a*) thickening of the tunica media, this thickening being primarily a true hypertrophy, although it may ultimately show some degeneration; (*b*) thickening of the tunica intima from fibrous hyperplasia of the subendothelial connective tissue without atheromatous degeneration; and (*c*) in some instances fibrous thickening of the tunica adventitia. 4. The changes in the arteries *in* the kidneys differ from those in the radial, or even in the renal arteries themselves before they enter the kidneys. They differ in the following respects: in the kidney the thickening of the intima is proportionally greater, the media is not appreciably thickened, it may even be atrophied and may have undergone hyaline degeneration. (The atrophic changes in the kidneys are in proportion to the sclerotic changes in the vessels.) 5 The lumen of the radial arteries and of the arteries in the kidneys is markedly diminished. 6. The changes in the nutrient arteries of the brain, and probably of the cord, correspond with those in the arteries inside the kidneys. 7. Arterio-sclerosis may be associated with more or less atheroma in the same subject.

My cases contradict Thoma's view that the thickening of the intima is compensatory to weakening and yielding of the media. In only one of my cases would the condition of the radial artery lend any support to this view. Fig. 1 represents the radial artery in this case and it will be seen that the vessel has a large lumen, that the muscle coat shows degeneration, and that the intima is thickened. Although this was the condition of the radial artery the changes in the kidney vessels corresponded with the changes in my other cases. Fig. 3 and Fig. 5, which are typical examples, represent the radials from two of my cases and show the small lumen, the thickened media, and the thickened intima Fig. 4 represents the kidney from the same case as Fig 3 and shows the marked thickening of the intima without thickening (perhaps even some atrophy) of the media Fig. 6 represents the kidney from the same case as Fig 5 and shows the great thickening of the intima, going on to occlusion of the lumen of the vessel, and along with this the atrophy and disappearance of the media as a distinct structure This case is the one in which Dr. Ford Robertson examined the nutrient arteries in the brain, and the changes in them correspond with the changes here described in the kidney.

In only one of the series which I have examined was there atheroma of the radial artery and in none was there atheroma of the kidney vessels. In some of the cases there was hardly any atheroma of the large arteries The thickening of the intima in the arteries of the kidney goes on to complete occlusion of the vessels affected; it cannot, therefore, be compensatory in the sense in which Thoma and his followers apply the term. Were it compensatory it should cease with the establishment of compensation.

Much of the confusion and difference of opinion which characterise writings on the kidneys and arteries have, I think, arisen from a failure to separate the points of similarity and of dissimilarity in the changes which occur in the arteries inside and outside the kidney. Inside the kidney the changes are most marked in the intima; outside it the changes are most marked in the media. In both, however, the intima is thickened. Inside the kidney the media may disappear and it often atrophies; outside the kidney this never occurs. In two of my cases the change in the radials was almost a pure hypermyotrophy such as Savill described, and it is interesting to note that in one of these there was a diffuse kidney cirrhosis with only slight thickening of the intima of the kidney arteries. Did time permit I might enlarge upon the relations of kidney and arterial change, but this must meanwhile be left. Fig. 2 represents this almost pure hypermyotrophy, and so far as I can at present see this is the only condition which may not be clinically distinguishable or at least not readily distinguishable from arterio sclerosis.

Clinical aspect of arterio sclerosis.—If we now turn to the clinical side of arterio-sclerosis the diagnosis rests primarily upon the condition of the radial arteries, supplemented by observations on the temporal and other vessels of corresponding size readily accessible to observation. The condition of the radial artery is taken as an index of the condition of vessels beyond direct examination. When brain, heart, or renal symptoms are present along with changes in the radial they are referred, in the case of the brain and heart, to the condition of the nutrient arteries of these organs. The changes are presumed to be of the same nature. In a case with renal symptoms the condition of the radial artery forms a large part of the foundation warranting a diagnosis of marked kidney change. The vessel is indurated and its wall is thickened; the induration is uniform, and the vessel, as felt upwards along its course, has been compared to whip-cord or to other substances. The truest comparison is to be found in the difference which, to

any educated finger, exists between a thin-walled and a thick-walled piece of rubber tubing of the size of an average radial artery. The uniformity of this thickening distinguishes the condition from atheroma where the thickening is irregular and may present areas of calcification. This thickened condition of the radial wall is often spoken of clinically as "high tension." This error has arisen from the fact that in high tension the artery feels cord-like, and thus all cord-like pulses are often loosely spoken of as high-tension pulses. The error is a very grave one, for the thick-walled vessel may have a very low pressure blood-stream; and the word "tension" in this connexion is used as if it were synonymous with pressure and as if the thick vessel always, and necessarily, meant high pressure. Indeed, it would be wise to abandon this word "tension" altogether until it came to be properly applied to a condition of the vessel wall alone and had clearly separated from it any application to blood-pressure. In anything I may say here I shall use the term "blood-pressure" in its correct sense.

Another common clinical error is to speak of a thickened radial artery as atheromatous, there being a widespread idea that thickening in arteries is synonymous with atheroma.

Arterial tonicity and hypertonus.—In the next place I wish to emphasise a feature of the pulse—including therein as is commonly done the condition of the arterial wall as well as the blood wave—which is largely ignored. I refer to the state of contraction of the vessel wall. Relaxation is recognised, in acute pneumonia for instance, and its significance is not overlooked, but is regarded as an indication for certain therapeutic measures. Arterial spasm, on the other hand, is recognised in angina pectoris and in some renal and other diseases. With the exception, however, of certain definite maladies, of which those mentioned are examples, there is little or no attention directed to this factor. The fact of a varying degree of contraction in arteries is really not open to question and the point does not require to be elaborated; in fact, I think that it is the recognition of this which has led to the confusion of the terms "tension" and "blood-pressure." In physiological conditions of perfect health when the arteries are tightened up, that is, contracted beyond their ordinary, the blood-pressure is raised because the vigour of the left ventricle is unimpaired. This heightening of blood-pressure inside a vessel necessarily, then, implies an increase of tension of its wall. On the other hand, a vessel may be tightened up without the blood-pressure being raised. This occurs when there is an accompanying diminution in ventricular force. In a certain sense even this tightening up of a vessel may be spoken of as "tension" (quite apart from the pressure exerted on its wall by heightening of blood-pressure), but the word is not used in medicine in this sense, otherwise extra contraction of all involuntary muscle, by nervous or other influences, would be spoken of as "tension," whereas "spasm" is the word used.

Spasm, it must be remembered, is only an exaggeration of the normal condition in muscle which is known as "tone" or "tonicity," and it is to this exaggerated tonicity in the vessels that I have ventured to apply the term "hypertonus." The word "spasm" has in medicine too restricted an application to make it suitable for my present purpose. The condition which I have in view is a prolonged or oft-recurring increase of the normal degree of contraction which vessels have in virtue of their muscle coat, and which is physiologically called "tonus." Hypertonus carries with it an important influence on the circulation apart from any alteration in blood-pressure—namely, a diminution in the blood-containing capacity of the vessels from a diminution in their internal diameter. This diminution in lumen necessarily occurs when an active contraction of the vessel wall is present. In diseased conditions it has very important results and determines symptoms of grave significance, to which reference will presently be made.

Recognition of hypertonus.—We have next to inquire how this condition of hypertonus can be recognised clinically. In the first place it can be either recognised, or suspected, by the educated finger. I have recognised the condition for years and acted on its recognition. With the assistance of my friend Dr. Oliphant Nicholson I have, however, been able to demonstrate the existence of this condition. I took cases where by means of the finger alone I judged that there was this recurring hypertonus. I argued that, if I were correct, the radial artery ought to give a diameter varying with the degree of tonus, and this is precisely what we found to be the case. The measurements were made by means of Oliver's arteriometer. By this instrument the diameter of an artery can be determined, and we found that when the vessel to my sense of touch was in the condition of hypertonus its lumen was smaller than when my finger told me that the hypertonus had passed off. We further took sphygmographic tracings from the artery and found that the arteriometer measurement and pulse-tracing helped to explain each other. I do not, however, wish it to be thought that arteriometer and sphygmograph are necessary to enable the clinician to recognise this condition, for they are not.

To illustrate the existence of hypertonus I direct your attention to sphygmographic tracings and arteriometer measurements from four cases.

CASE 1.—A man, aged 35 years, came to me at the Edinburgh Royal Infirmary complaining of headache and general weakness and insomnia. He was a strongly built, well-nourished man, but was somewhat pale. He had been working at his occupation for three months and before that time had been well. The radial artery was markedly thick, the thickening being uniform and extending right up the arm. In fact, it presented the characters which would commonly be described as "arterio-sclerotic." The man was young, and this, combined with his symptoms and the absence of any evidence in the urine of renal disease, led me to surmise that this vessel condition was largely one of hypertonus and that, even assuming that there might be some degree of thickening, his complaints were due to the hypertonus and to the causes producing it. An arteriometer measurement and a sphygmographic tracing were taken and he was admitted into Ward 23. Some doses of erythro-tetranitrate demonstrated that hypertonus was accountable for most, but not all, of the radial thickening; this substance, as is well known, relaxes arterial spasm, but does not, of course, remove an organised thickening, and in this case it greatly reduced the thickening by relaxing the spasm. The arteriometer measurement and the sphygmographic tracings can be compared with the former ones. Tracings 1 and 2 were taken before and after giving erythro-tetranitrate and the arteriometer measurements were 2·3 and 2·7 millimetres. The existence of hypertonus in this case is of special interest, as we found afterwards that the man had had syphilis.

CASE 2.—The next tracings were also from a patient in Ward 23 suffering from spasmodic asthma. He was a man, aged 53 years, and it was quite clear that when the asthmatic spasm supervened his radial arteries became markedly tightened up. The following are the pulse tracings (Tracings 3 and 4) during the asthmatic spasm, and after its relief by means of liquor trinitrina the arteriometer measurements were respectively 2·2 and 2·4 millimetres.

CASE 3.—The next tracings (Tracings 5 and 6) were from a man, aged about 60 years, also in Ward 23, suffering from extreme orthopnœa, believed to be of cardiac origin and due to myocardial degeneration. The vessels were thickened, but they also seemed to me to be in a condition of hypertonus. He got great relief from the administration of antispasmodics. The arteriometer measurements were respectively 2·4 and 2·7 millimetres.

CASE 4.—The next tracings are from an old man, aged 70 years, who was under my observation for years in Queensberry House. He was subject in his later years to recurring attacks of "renal asthma," during which his permanently-thickened vessels quite appreciably tightened up and became thicker. The sphygmograph gave the following traces (Tracings 7 and 8) during the attacks and in the intervals, and the arteriometer gave the diameter of the vessel as 2·2 and 2·6 respectively.

In these four cases the difference in the pulse when tightened and not tightened was readily appreciable by the finger. The sphygmograms bear out this, while the arteriometer reading of the diameter of the radials under the two conditions explains the sphygmograms. Under hypertonus the swing of the lever is less, the percussion stroke is shorter and less abrupt, the summit tends to be more rounded, and the predicrotic notch less evident. When the hypertonus passes off all this is altered.

Cases in which hypertonus occurs.—Hypertonus occurs in normal arteries and in sclerosed arteries. It occurs in the young, the middle-aged, and the old. In fact, I would specially impress upon you the fact that even in thickened arteries, showing arterio-sclerosis, this tightening up which I have called "hypertonus" occurs. This combination was present in three or four of the cases from which the pulse tracings were taken. Now if this not only can, but does, TRACING 1 (CASE 1).

occur, the idea of muscular degeneration, with which the literature on arterio-sclerosis is saturated, and consequent inability on the part of the artery materially to respond to nerve or blood influences must be materially modified. Not only this but the recognition of this element or factor of hypertonus in sclerosed arteries is, indeed, of supreme clinical importance. Did time permit I could illustrate this point with numerous cases with symptoms referable in one case to the brain, in others to the spinal cord, heart, lungs, or kidney. In all the symptoms are mainly attributable to the hypertonus lowering the blood-supply to organs which are already badly supplied by the sclerosed arteries I shall only briefly refer to three cases.

CASE 5 —The patient was aged 70 years. He had markedly thickened arteries, arcus senilis, and no albumin. He began to be unusually somnolent during the day, his gait became somewhat unsteady and his speech somewhat thick, he could not concentrate his mind, and he noticed that in writing letters he misspelt common words. His arteries were tightened up but the blood-pressure was not high. Under treatment directed to the relief of hypertonus the symptoms entirely passed off and he has continued in good health for nearly two years

CASE 6 —The patient was a very old but active man who had been rather out of sorts for a week or two. He had thickened arteries and no albumin He suddenly one day became delirious and was kept in bed. His arteries were tightened up without any increase in his blood-pressure. Under treatment directed to the relief of the hypertonus the delirium became daily less and finally disappeared.

CASE 7 —The patient was a man, aged 60 years, who had been under my observation in Queensberry House since July, 1899 When admitted he had very thick vessels, but there was no albumin in the urine. After admission he had several attacks of "uræmic coma," in each of which I thought he would die. Although his vessels were amongst the thickest I had seen, arteriometer measurements confirmed my observation that even they varied in diameter Acting on the same lines this man recovered and has not had an attack for over a year.

Cause of hypertonus.—We now come to the question of the cause of hypertonus. The condition can, and does, occur at all ages. In strong people it is associated with, and part of, heightened blood-pressure and a pulse of true high tension.

In aged people with a relatively feeble or failing heart hypertonus does not lead to an increase in blood-pressure but to the reverse. In fact, it is not infrequently the precursor of heart failure. At all ages the condition, in the great majority of cases, is produced by the introduction of poisons into the body or by an auto-intoxication. The question of auto-intoxication is of great interest in this connexion, for it is due to physiological error along one or other of two lines. It may be, and often is, due to physiological errors in primary digestion with the absorption of toxins from the gastro-intestinal tract. In other instances it is due to errors in the processes included under secondary digestion, such as retention of waste matters and imperfect katabolism. The latter occurs in the aged, in gouty and rheumatic people, and in the sedentary. The former is perhaps more common in young adult life The condition is present, probably, in all diseases in which there is absorption of deleterious substances. It may even be caused by syphilis, and manifest itself, as in one of the cases I have referred to, before there is much permanent thickening of the vessel wall.

Connexion between arterio-sclerosis and hypertonus.—This brings me to the final question as to the relationship between arterio sclerosis and hypertonus. I connect them thus: recurring or continued hypertonus leads to hypertrophy of the muscular media of the arteries under the physiological law that increased action in muscle leads to its hypertrophy. I am not concerned at present to inquire how the increased action is brought about; I content myself by showing its existence. This accounts for the thickened media. The thickened intima is to be explained by the circulation in the blood of deleterious substances of various kinds; these substances act on the subendothelial connective tissue, irritate it, and lead to its hyperplasia. We thus get the completed picture of arterio-sclerosis. The evolution of the changes occupies a varying time in different persons; in some the hypertonus comes early in life, and in early middle age sclerosis is established. In some there is little physiological error, hypertonus is but an occasional occurrence, and sclerosis appears late in life. The capability of the arteries to contract when an excess of toxin is present is in my experience seldom lost, and that is the reason why the recognition of it in sclerosed vessels is a matter of such great practical importance. While for the present I do not deal with the behaviour of the capillaries, it is not to be understood that I ignore their presence, their reactions, or their influence in some of the conditions touched upon in this paper.

Edinburgh.

THE BACTERIOLOGY OF SPORADIC CEREBRO-SPINAL MENINGITIS.

BY WILLIAM HUNTER, M.B., C.M. ABERD.,
ASSISTANT BACTERIOLOGIST TO THE LONDON HOSPITAL;
AND
ALEXANDER W. NUTHALL, F.R.C.S.
(*From the Bacteriological Laboratory, London Hospital.*)

FOR years the etiology of meningitis was involved in obscurity. The early observations of Murchison, Richardson, and others, suggesting the origin of the disease from articles of diet, telluric influences, &c., have now only a historic interest. The more recent investigations tend to show that micro-organisms play an extremely important rôle in the production of the disease. The early bacteriological investigations, however, are of little value owing to the deficiencies then existing in technique, so that in dealing with the subject at present the investigations of Klebs, Eberth, and others may be passed over.

The first step to determine the exact micro-organismal nature of meningitis was taken by Gaucher[1] who as early as 1881 demonstrated the presence of micrococci in the blood of a patient suffering from meningitis, as well as in the meningeal exudate after death. In 1883 Leyden[2] and Ughetti[3] described, more or less accurately, the presence of large round or oval micrococci in the exudation obtained from the meninges in a case of sporadic cerebro-spinal meningitis. In 1884 these observations were confirmed by Marchiafava and Celli[4] who showed the presence of micrococci not only free in the exudate but also in the protoplasm of the leucocytes forming part of the exudation. In 1886, during an epidemic in Cologne, Leichtenstern[5] invariably found in the meningeal exudation micrococci which he likened to gonococci.

Although these investigators succeeded in demonstrating the invariable presence of large numbers of micrococci in the meningeal exudate and pial tissue, they failed to cultivate them and to determine exactly their etiological significance. This step was taken by Weichselbaum[6] who in 1887 gave the first accurate description of the apparently causative agent at work in the production of the disease. Weichselbaum investigated in all eight cases. In two of these he found diplococci which morphologically resembled pneumococci. In the remaining cases, however, no pneumococcic-like organisms were found, but diplococci which always occurred in pairs, varied much in size, and resembled gonococci. They were present for the most part in the protoplasm of the leucocytes and, what was extremely important, they decolourised when treated by Gram's method of staining. These observations were subsequently confirmed by the extensive researches of Foà and Bordoni-Uffreduzzi,[7] Goldschmidt,[8] Netter,[9] and others.

Although it was admitted by the majority of observers that a diplococcus was invariably found in the meninges in cases of meningitis, considerable difference existed as to the exact nature of the micrococcus. Many regarded it as the pneumococcus of Fraenkel or a variety of this. For instance, Foà at the Tenth International Medical Congress in Berlin in 1890 concluded that this diplococcus, or so-called "meningococcus," was simply a variety of the pneumococcus and could under certain conditions be converted into the latter and *vice versâ*. Righi,[10] Quadù,[11] and other members of the Italian school gave much support to this observation and deduced from their researches that the diplococcus found in cases of meningitis was simply a modified form of the pneumococcus, and, further, that meningitis was to be regarded as a local manifestation of a general diplococcic infection—in fact, a diplococcæmia. Further, the French school, headed by Netter, is also inclined to regard the diplococcus of Weichselbaum as a variety of the pneumococcus. The presence of these micrococci in the cells of the exudate they look upon as evidence of degeneration and phagocytosis, a view which is improbable in the light of recent research. They are supported in their observations by the work of Lenhartz,[12] Hunermann,[13] Vincenzi,[14] and others.

It is admitted that the pneumococcus may produce a meningitis or be present as a secondary infection. And this is not at all remarkable, as the pneumococcus is now known to be an organism of wide distribution. The fact, however, that meningitis often complicates pneumonia, or *vice versâ*, is no criterion that the pneumococcus is the specific agent at work in the production of the disease—cerebro-spinal meningitis—as we know it in its epidemic and sporadic forms. In reality there is every reason to believe that the diplococcus described by Weichselbaum is something very different. Further, there is much reason to doubt whether the cocci described by those who have investigated cases of meningitis were pneumococci. Kamen,[15] for instance, quotes the observations of Panienski[16] who reported in all 13 cases as due to pneumococcus, but advanced insufficient evidence to prove conclusively that the micro-organisms in question were in reality pneumococci. During the last few years the original researches of Weichselbaum have received much support and confirmation. The observations of Jaeger[17] in 1895, Heubner,[18] Councilman, Mallory and Wright,[19] and Osler[20] advance extremely strong evidence in favour of the view that Weichselbaum's diplococcus is the specific agent at work in the production of cerebro-spinal meningitis in its epidemic and sporadic forms Heubner, for instance, was able to reproduce the same train of symptoms and pathological changes in goats by injection subdurally of pure cultures of this micro-organism isolated from cases of cerebro-spinal meningitis in man.

From this review of the most important literature it is at once evident that even at present considerable difference of opinion exists as to the exact nature of the micrococci found in the meningeal exudate in cases of meningitis. Apart from the fact that cases of meningitis may under certain conditions be due to a great variety of micro-organisms, as staphylococci, streptococci, bacillus influenzæ, bacillus typhosus, bacillus coli, &c., the positions taken by the leading authorities at present may be said to be the following: the French doctrine, that cerebro-spinal meningitis in its epidemic or sporadic form may be caused either by the pneumococcus or the diplococcus intra-cellularis of Weichselbaum; the German and American doctrine, that the diplococcus intra-cellularis meningitidis of Weichselbaum is, in all probability, the specific agent in epidemic or sporadic cerebro-spinal meningitis, the pneumococcus being of secondary importance. In 1898 Still,[21] in two interesting articles on Posterior Basal Meningitis in Children, was inclined to regard this disease as merely a sporadic manifestation of cerebro-spinal meningitis. His conclusion was supported by the bacteriological examination of a number of cases in which he found the invariable presence of intra- and extra cellular diplococci. These diplococci resembled morphologically the diplococcus intra cellularis meningitidis described by Weichselbaum. Up to the present time Still's observations have received no confirmation. His conclusion that posterior basal meningitis is simply a sporadic manifestation of cerebro-spinal meningitis and is caused by Weichselbaum's diplococcus certainly warrants further investigation as his results when developed will clear up many points in regard to sporadic meningitis and its relation to the disease in its epidemic form.

Recently we have had the opportunity of examining bacteriologically cerebro-spinal fluid obtained by lumbar puncture from nine cases of meningitis in children and from one case in a young adult It was difficult from a clinical point of view to determine the exact nature of these cases of meningitis—in fact, it was impossible to say with any degree of certainty whether they were simple or tuberculous. On this account lumbar puncture was performed and the results of the bacteriological examination of the cerebro-spinal fluid obtained from these cases proved of the utmost value in regard to the determination of the exact nature of the morbid process present.

At this point we would like to express our gratitude to Dr. Percy Kidd, Dr. Gilbart Smith, Dr. Warner, and Dr. Sansom for their kindness in allowing us to make use of the cases clinically, and to Dr. Schorstein and Dr. Hadley for the large amount of pathological material which they have freely placed at our disposal.

CASE 1.—The patient, a girl, aged seven years, was admitted on Feb 17th, 1901. She had been ill for six days, suffering from headache, restlessness, and incontinence of urine. Her temperature on admission was 104° F., the pulse-rate being 148, and the respirations 36 There were marked retraction of the head, twitching movement of the facial muscles of the right side with left facial paralysis, and strabismus The fundi were normal; later, spasmodic movements of the left arm set in. Kernig's sign was present Death from exhaustion took place on Feb. 22nd. At the post-mortem examination extensive and scattered purulent exudation over the hemispheres with a large amount of purulent lymph in the inter-peduncular space was found. There was a large quantity of clear fluid in the ventricles. Over the whole length of the spinal cord there was a considerable amount of purulent exudation. The lungs showed marked broncho-pneumonia The other organs appeared to be healthy. There was no evidence of tubercle.

Lumbar puncture was performed a day or two before death. The fluid obtained was turbid and after centrifugalisation the deposit was examined microscopically for micro-organisms. Diplococci were found in fairly large numbers. Many occupied an intra-cellular position. They did not retain the stain well by Gram's method and decolourised completely by Claudius's method. A well-marked capsule was present. Considerable quantities of the fluid were transferred to tubes containing blood-serum, ascitic fluid bouillon, and glycerine agar and were incubated at 37° C.

CASE 2.—The patient was a boy, aged three years, who was admitted on Jan 30th, 1901. He had been ill for two months with progressive emaciation and frequent attacks of "cramp." The following was his condition on admission. There were marked cervical opisthotonos and strabismus, but no optic neuritis, aural discharge, or convulsions. The knee-jerks were exaggerated. There was incontinence of urine and fæces Death occurred from exhaustion on March 4th. Post mortem there was found to be slight milky opacity of the meninges over the base, but there was no marked exudation. The ventricles were much distended with clear fluid. The other organs were healthy and there was no evidence of tubercle.

Lumbar puncture was performed on Feb. 25th. The fluid obtained was clear After centrifugalisation the deposit was examined microscopically and was found to contain leucocytes and intra- and extra-cellular diplococci. Tubes of ascitic fluid bouillon, blood-serum, and glycerine agar were inoculated with large quantities of the fluid and were incubated at 37° C.

CASE 3.—The patient, a girl, aged two and a half years, admitted on Feb 14th, 1901, had been ill for two months with wasting, nausea and vomiting. Her condition on admission was one of great emaciation. There was no rigidity, retraction of the head, or paralysis, but there was apparent hyperæsthesia of the legs. She was semi-comatose. Later there were strabismus and nystagmus, but no optic neuritis, rigidity of the arm, or convulsions. Kernig's and Babinsky's signs were present. Death from exhaustion resulted. A considerable quantity of blood-stained and opalescent fluid was found post mortem in the meningeal spaces. Over the basal and posterior parts of the brain and the ventral surface of the cerebellum there was extensive purulent exudation. The cerebral convolutions were pale and flattened, the meninges covering them showing no change. There was extreme hydrocephalus The meninges covering the spinal cord, especially over the posterior columns, showed the presence of marked exudation and congestion. The other organs appeared to be healthy and there was no evidence of tubercle.

Lumbar puncture was performed on Feb. 27th. The fluid obtained was clear. The deposit obtained by centrifugalisation showed the presence of many diplococci, both intra- and extra-cellular, all of which possessed a marked capsule Tubes of blood-serum, ascitic fluid, bouillon, and glycerine agar were inoculated with considerable amounts of the fluid and were incubated at 37° C.

CASE 4.—The patient, a male infant, aged four months, admitted on March 2nd, 1901, had been for five weeks suffering from convulsions and retraction of the head. After admission there were constant diarrhœa and vomiting and marked cervical opisthotonos There was bulging of the fontanelle There was no strabismus, nystagmus, or optic neuritis Kernig's sign and Babinsky's sign were present. Since admission no convulsions had occurred.

Lumbar puncture was performed on March 8th. The fluid obtained was clear After centrifugalisation the deposit was stained with methylene blue. Capsulated diplococci were present, most of them being intra-cellular. They decolourised by Gram's method. Cultures were made exactly as in the previous cases.

CASE 5.—The patient was a girl, aged six years, who was admitted on March 8th, 1901. She had been suffering for 10 days from headache, vomiting, and general irritability. On the day of her admission she had a convulsion which was followed by coma When admitted the patient was comatose and her temperature was 101° F. The pupils were dilated and there were strabismus and nystagmus, but no optic neuritis was present The head was turned to the left. There were rigidity and rhythmic movements of the left arm and leg, but there was no rigidly of the neck. Kernig's sign was present. There was incontinence of urine and fæces. Later retraction of the head developed, with coma and slight optic neuritis. These symptoms became progressively worse and death occurred on March 13th. Post-mortem examination

Presence of other micro-organisms	—	A minute, non-motile, non-Gram staining bacillus. Probably bacillus influenzæ	—	A minute bacillus as in Case 2. Very like bacillus influenzæ.	Staphylococcus albus and citreus also present.	Tubercle bacilli. Marked tuberculous meningitis.	—	Large capsulated non Gram staining bacillus, also probably bacillus influenzæ.	Staphylococcus albus and aureus and large non-Gram staining bacillus.	—
Experimental inoculation	*White mouse*: ½ c.c. of 48-hours' ascitic fluid culture intra-peritoneally; *no result.* *Guinea pig*: 1 c.c. of same subcutaneously; *no result.* *Guinea-pig* 1 c.c. of same intra-peritoneally; *no result.*	*White mouse*: ½ c.c of 48-hours' emulsified agar culture intra-peritoneally, *no result.* *Guinea-pig*: 1 c.c. of same subcutaneously; *no result* *Guinea-pig*: 1 c.c. of same intra peritoneally; *no result.*	*White mouse*: ½ c.c. of 48-hours' bouillon culture intra peritoneally; *no result.* *Guinea-pig*: 1 c.c of same subcutaneously; *no result.* *Guinea-pig*. 1 c.c. of same intra peritoneally; *no result*	*White mouse*: ½ c.c. of 48-hours' ascitic fluid culture intra-peritoneally; *no result* *Guinea-pig*: 1 c.c. of same subcutaneously; *no result.* *Guinea pig*: 1 c.c of same intra-peritoneally; *no result.*	*White mouse*: ½ c.c. of 48-hours' emulsified agar culture intra peritoneally; *no result.* *Guinea pig*: 1 c.c. of same subcutaneously; *no result* *Guinea pig* 1 c.c. of same intra-peritoneally, *no result.*	—	—	—	—	*White mouse*: 1 c.c. of 48-hours' ascitic fluid culture intra-peritoneally; *no result.* *Guinea-pig* 2 c.c. of same intra peritoneally; *no result.* *Rabbit*: 2 c.c. of same intra-peritoneally and subcutaneously; *no*

showed marked congestion of, and exudation into, the meninges, especially over the basal regions of the brain. There was no marked exudation over the cerebral hemispheres. The ventricles contained an excess of clear fluid. There was no evidence of tubercle in the cranial cavity. The pericardium contained an excess of blood stained fluid. Its surface was granular owing to the presence of large numbers of small, sharply defined, greyish-white nodules which proved to be tuberculous. The neighbouring mediastinal lymph glands were the seat of marked caseation and from them the tuberculous process could be traced to the pericardium. The lungs were slightly œdematous. There was no evidence of tubercle. The other organs were apparently healthy.

Lumbar puncture was performed on the day on which the patient was admitted and it was followed by improvement in the general condition which lasted for a few hours. The deposit obtained after centrifugalisation of the fluid contained diplococci as in the previous cases. Cultures were made as before.

CASE 6.—The patient, a boy, aged one year and nine months, was admitted on March 13th, 1901. He had been ill for three months and had suffered from cough, general irritability, and retraction of the head. There was a history of congenital syphilis. On admission the child had convulsions, retraction of the head, a bulged fontanelle, and spasmodic movements of the left arm and leg. Kernig's sign was present, but there was no strabismus or optic neuritis The condition of the patient became rapidly worse and death took place on March 17th from exhaustion. Post mortem there was found to be considerable exudation into the meninges over the basal and posterior parts of the brain, but there was little or no change in the meninges over the cerebral hemispheres. The meninges around the basal and posterior parts of the brain were crowded with small grey tubercles. The ventricles contained an excess of lymph-like fluid. The thoracic and abdominal organs were the seat of an advanced miliary tuberculosis

Lumbar puncture was performed on March 14th. No diplococci were found on examination of the fluid immediately after it was withdrawn. The fluid was therefore incubated at 37° C. for 24 hours, after which diplococci were found in considerable numbers. Cultures were made as before.

CASE 7.—The patient was a female infant, aged three months, who was admitted on March 12th, 1901. The illness had lasted for five weeks with wasting and cough. Convulsions and vomiting had been present for a week before admission. On admission there were retraction of the head and strabismus but no optic neuritis. Kernig's sign was present.

Lumbar puncture was performed on March 15th. No diplococci were found in the fluid immediately after withdrawal. As in the preceding case, the fluid was incubated at 37° C. for 24 hours, after which microscopical examination of the deposit showed the presence of many capsulated diplococci Cultures were made as before.

CASE 8.—The patient, a boy, aged one year, was admitted on Feb. 28th, 1901. He was suffering from broncho-pneumonia A week after admission strabismus, retraction of the head, and general rigidity developed. Kernig's sign was present.

Lumbar puncture was performed on March 15th. The fluid obtained was incubated at 37° C. for 24 hours, after which diplococci were found as in the other cases. Further, a large capsulated and rod-shaped micro-organism and a small, non-motile bacillus were found. Like the diplococci, they did not retain the stain by Gram's method Cultures were prepared as before.

CASE 9.—The patient, a female infant, one month old, was admitted on March 11th, 1901, suffering from convulsions. Death took place three hours after admission. Post mortem there was found to be extensive purulent exudation into the meninges over both cerebral hemispheres. The ventricles were distended with fluid. The exudation was examined bacteriologically at once and was found to contain diplococci, many of which were intra-cellular. Cultures were made as in other cases.

CASE 10.—The patient was a woman, aged 38 years, who was admitted on March 29th, 1900, complaining of headache, vomiting, and rash on the arms and legs. On admission there was marked retraction of the head. No convulsive movements were present, nor was there strabismus, optic neuritis, paralysis, or anæsthesia. While under observation she had repeated attacks of pain in the head and the back, accompanied by marked retraction of the head, profuse perspiration, inequality of the pupils, and delirium. The symptoms gradually improved and the patient was discharged on June 9th.

Lumbar puncture was performed on May 31st by Mr. F. S. Eve and from the fluid obtained numerous intra- and extra-cellular diplococci were found. Cultures were made as in the other cases.

Further details with regard to all of the foregoing cases are given in Table I. which is a short summary of the morphological and biological characteristics of the diplococci found in the cerebro-spinal fluid obtained from the cases.

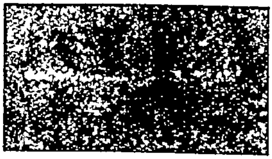
From this table it is evident that there exist two more or less definite varieties of diplococci which from their staining reactions and cultural peculiarities may be distinguished from each other:—

TABLE II.

—	Type A.	Type B.
Staining characteristics	Gram-indefinite, usually negative.	Gram-positive.
Agar and glycerine agar	Growth extremely delicate; colonies are very transparent.	Growth luxuriant; colonies are viscid and tend to run together.
Gelatin	Growth very delicate; no liquefaction.	Growth slight, if any; no liquefaction.
Bouillon	Growth slight.	Growth good; marked turbidity.
Stiffened blood serum	Growth resembles that on agar.	Growth good; colonies porcelain like
Potato	Slight growth; invisible	Growth good; viscid.
Cases......	1, 2, 4, 5, 6, 7, 10.	3, 8, 9.

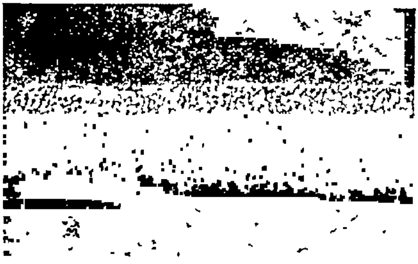
These results correspond more or less accurately with the descriptions given recently by Pfaundler[22] who distinguished two distinct varieties of diplococci in the cases which he examined. He tabulated the micro-organisms described by previous investigators and found that they could be grouped under two heads. Thus, the diplococci found by Weichselbaum, Bernheim and Moser, and Councilman and Pfaundler (three cases) formed one group, the

FIG. 1.



Type A, growth on agar, 48 hours old.

FIG. 2.



Type B, growth on agar, 48 hours old.

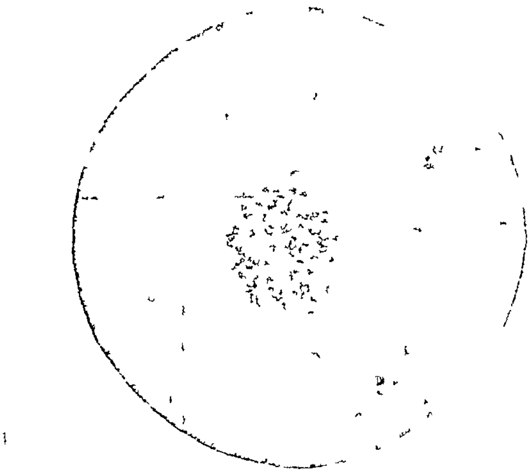
---

[22] Jahrbuch für Kinderheilkunde, Band xlix, 1899, p. 264.

characteristics of which correspond almost exactly with our Type A, while those diplococci described by Jaeger, Heubner, Urban, Still, and Pfaundler (two cases) formed a second group which corresponds with our Type B.

Although the diplococci found by us are easily divisible into two groups, we have every reason to believe that they represent probably one and the same micro organism.

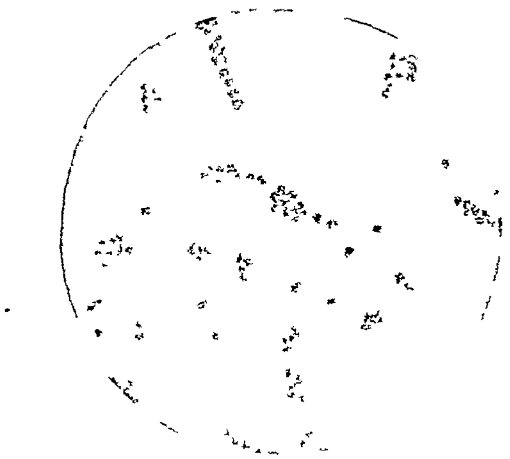
FIG. 3.



Polymorpho-nuclear leucocyte containing diplococci.

Morphologically no point of distinction is to be made out. Their resemblance to gonococci, their extreme variability in size and shape, combined with the invariable presence of a marked capsule even in cultures, all point to their similarity. The fact that the majority of strains (Cases 1, 2, 4, 5, 6, 7, and 10) present extreme delicacy in growth on such media as agar, glycerine agar, and blood serum, &c., and that the remaining strains (Cases 3, 8, and 9) grow more luxuriantly on the above mentioned media, does not seem to warrant us in drawing any absolute distinction between the two varieties or in disproving their identity. Our own results would rather seem to show that they are one and the same micro organism, and that the differences noted in the types described are only those which are constantly being met with in the fuller knowledge of any micro-organism. Further, the cases presented no corresponding points of distinction clinically, and we are inclined to agree with Pfaundler that, although slight differences are to be observed in regard to the biological characters of the micro-organism, they are without influence on the course of the disease.

FIG. 4.



Diplococcus intracellularis in pure culture, stained by Gram's method.

A point of extreme interest in regard to those diplococci is the constant negative result obtained by experimental inoculation. Even although large doses of living cultures of the diplococci were introduced intra-peritoneally as well as subcutaneously into mice, guinea-pigs, and rabbits, absolutely no lethal result was obtained. Unfortunately we did not have it in our power to extend the interesting results obtained by Heubner who succeeded in producing an undoubted cerebro-spinal inflammatory process by subdural inoculation in goats of diplococci isolated from cases of cerebro spinal meningitis in man. Although we have always succeeded in isolating the diplococcus, in only four of the cases has it been present in pure culture. The following is a summary of the results which we have obtained. In four cases (Cases 1, 3, 7, and 10) the diplococcus was present in pure culture. In three cases (Cases 2, 4, and 8) the diplococcus was associated with a bacillus which from its morphological and staining characteristics we are inclined to regard as the bacillus influenzæ Pfeiffer. In two cases (Cases 8 and 9) the diplococcus was associated *with a large capsulated bacillus which morphologically* and biologically agreed with the descriptions given by Centanni and Neumann[23] of a bacillus called "bacillus meningitidis," and found by them in the meningeal exudate in cases of meningitis. In two cases (Cases 5 and 9) the diplococcus was associated with ordinary pyogenic cocci, probably the result of accidental contamination. In one case (Case 6) the diplococcus was associated with the bacillus tuberculosis.

These results are in entire harmony with the observations of other investigators. The association of a bacillus which from our researches we have reason to believe was the bacillus influenzæ with the diplococcus intra-cellularis is interesting. Although Pfuhl,[24] Nauwerk,[25] Högerstedt,[26] Leichtenstern,[27] and others have demonstrated the presence of Pfeiffer's bacillus influenzæ in the meningeal exudate in cases of suppurative meningitis and even go so far as to believe in the existence of a specific form of meningitis—meningitis grippalis—only two cases have been reported up to the present where this micro-organism has been demonstrated by lumbar puncture—one by Slawyck,[28] a case of general influenzal infection, lumbar puncture being performed owing to the severity of the meningeal symptoms the other by Lander[29] who investigated a similar case.

Within recent years it has been shown that the association of the diplococcus intra-cellularis with the bacillus tuberculosis is by no means uncommon. Since Holdheim[30] demonstrated this fact quite a large number of confirmatory and detailed accounts have been given—notably by Heubner,[31] Lenharz,[32] Netter,[33] and quite recently by Pfaundler. Not only have some of these observers found this association in the meningeal exudation post mortem, but also in the cerebro spinal fluid obtained by lumbar puncture during life. In our case there was no question as to the existence of a general tuberculosis. The liver, the spleen, the lungs, and the kidneys were crowded with typical miliary tuberculous nodules and the meninges, especially around the posterior and basal parts of the brain, were the seat of a definite tuberculous process. This case clearly shows the importance of making a thorough bacteriological investigation during life as well as post mortem. If no such examination had been undertaken the case would undoubtedly have been regarded as an uncomplicated case of tuberculous meningitis. The examination of the cerebro-spinal fluid during life combined with that of the meninges post mortem, however, conclusively proved that the case was one of mixed infection.

In Case 5 an interesting result was obtained post mortem. Lumbar puncture was made during life and the cerebro-spinal fluid was found to contain large numbers of typical diplococci Post mortem the meninges showed the expected posterior and basal exudation. No evidence of tubercle was present. On examining the thorax, however, the pericardium was found to be the seat of a marked tuberculous process and the neighbouring mediastinal lymph glands were the seat of caseation. From the latter the tuberculous process could be traced to the pericardium. The other organs were healthy.

In conclusion we would urge the following: 1. *That in all* the cases of meningitis examined by us a diplococcus has [illegible] spinal fluid. In nine of these [illegible]

coccus was present in pure culture, in others associated with other micro-organisms—e g, bacillus influenzæ and bacillus tuberculosis. 4. That the clinical picture and the pathological changes found in these cases are those met with in so-called "posterior basal meningitis." 5. That in all probability "posterior basal meningitis" is simply a sporadic manifestation of cerebro spinal meningitis and is produced by the same micro-organism—namely, the diplococcus intracellularis meningitidis.

ON THE OPERATIVE TREATMENT OF CORNEAL ASTIGMATISM

BY A BREUER, M D FREIBURG, M R C S ENG, L R C P LOND

THE changes in curvature of the cornea resulting from operations—e g, extraction of cataract, iridectomy, &c—are well known. Although these changes are lessened as time goes on, still a very considerable part of them remains permanent. In the now often practised operation for high myopia the ophthalmic surgeon has taken care so to localise the incision as to produce the minimum of astigmatism, or if a marked degree of astigmatism was present before the operation to diminish it by the incision.

Several authors (Bates,[1] Pflüger,[2] Lucciola[3]) have attempted to cure astigmatism by corneal incisions with the keratome or with a Graefe's knife. The incisions were usually made at one or both ends of the meridian of stronger refraction. In some cases the astigmatism became less and even disappeared completely. Similar observations were made by Bocci[4] and Laus[5] in the rabbit. The last named author studied the effects of a perforating wound made with the keratome and of a non perforating wound made with the galvano cautery, advocating the latter. Reymond[6] studied the effect of incisions in the limbus corneæ and of sub conjunctival scarification of the sclera (from three to four millimetres behind the limbus). He collected his results as follows. The result of an incision depends on its location, whether in the sclera, the limbus, or the periphery of the cornea. The curvature is always changed in both meridians, the one which contains the incision and the one perpendicular to it. Incisions in the outer border of the limbus corneæ and sclera generally produce an increase of curvature in the corresponding meridian, those in the clear cornea a decrease of curvature (lengthening of the corneal radius).

Within the last three years I have always noted the refraction of the cornea in the visual line in the two principal meridians before and after any operation by means of Javal's ophthalmometer (Kagenaar, Utrecht). Without a single exception I found that corneal incisions made, *for instance*, in the vertical meridian lessen the refraction of that meridian and increase at the same time that of the horizontal. If the incision is made in the limbus or still a little further peripherally, as in iridectomy for glaucoma, the effect is small; the more the incision approaches the centre of the cornea the greater the effect. All my observations were made on eyes free from any apparent previous disease such as trachoma, scrofulosis, ulcers, &c. In order to study the changes more closely I measured the curvature of the cornea not only in its visual centre, but in points 5°, 10°, and 15° distant from it along the principal meridians. In representing these measurements by a curve I followed Sulzer's[7] suggestion. He recorded his measurements in the so-called "diagramme dioptrique." First he measures the refraction of the two principal meridians (mostly vertical and horizontal) at the point where the visual line passes through the cornea while the patient looks at the centre of the ophthalmometer. Next the patient is asked to look in succession at points situated in the principal meridians at 5°, 10°, and 15° towards the nasal and temporal side, above and below the axis of the ophthalmometer. We can utilise as an object for fixation the division on the keratoscopic disc of Javal's ophthalmometer (model 1889), or white dots can be marked on a piece of wire fixed to the instrument in the principal meridians at 5°, 10°, and 15° from its axis. As the reflected corneal images become too indistinct when measuring beyond 20° from the centre only a small central part of the cornea can be represented in this manner. A distance of 15° is considered quite sufficient by Sulzer (15° = 2 millimetres in corneæ of medium refraction). For each of the above points the refraction is measured by bringing the two central images in contact in the centre of the vision-field of the instrument; the number of dioptres is read off on the division of the arc. The measurement will become plain in the accompanying diagrams. The horizontal (abscissa) of the two intersecting straight lines serves as a basis for the diagram of the horizontal meridian or that which is nearer to the horizontal one. The figures 5, 10, 15, show the distance in angles of the points measured from the visual line of the cornea. Each division on the vertical line represents one dioptre. For simplification the figure 40 (dioptres) is placed at the intersection of the vertical and horizontal lines; therefore the refraction of the points measuring more than 40 D is marked above, and that of those measuring less than 40 D below, the horizontal axis. The observations for the temporal half of the right eye are marked on the right side of the diagram, those for the nasal half on the left side. For the left eye the marking is reversed, so that the diagram represents the cornea as the patient would see it in a plane mirror. After having marked the refraction for the different points measured these marks are united by a plane curve. In order to register the refraction of the vertical meridian the arc of the ophthalmometer and the diagram are turned 90°. The vertical line of the diagram, which becomes horizontal now, represents the angular distances, while the axis previously horizontal marks the dioptres. The first diagram illustrates the changes in corneal curvature after an iridectomy for glaucoma.

CASE 1. *Glaucoma chronicum simplex*.—The patient was a man, aged 59 years. T + 1. Ophthalmometer L $\pm$ 0 (i e, no corneal astigmatism). When any axis is mentioned it is the one of less refraction. The axis is marked as follows: ($\underbrace{180\ \text{R}\ 0}\underbrace{0\ \text{L}\ 180}$) Retinoscopy, L $\lfloor^{+0.5}_{\;0}$. VL = $\frac{6}{12}$ + 0.5 cyl — = $\frac{6}{9}$. The continuous curve I in Fig 1 shows the corneal curvature before the operation. In both meridians the refraction at the section of cornea with visual axis is about 43 D. On June 6th, 1900, iridectomy upwards for left glaucoma was performed. Normal healing followed an incision with a medium sized bent keratome. A week later the corneal refraction was *measured, and it is represented by the dotted curve II*. We see that the refraction of the vertical meridian is diminished in all the seven points measured. While this diminution is about 1.2 D in the centre it amounts to about 3 D at the upper end of the curve, the one nearest to the incision. In the horizontal meridian, however, the corneal refraction is increased all along the line by about 1 to 1½ D. Javal: L | $\pm$ 1.5. Retinoscopy: L $\lfloor^{+1.0}_{\;-1.5}$. V L < $\frac{6}{12}\frac{+0.5\text{ sph}}{-2.0\text{ cyl.}}$ < $\frac{6}{9}$. Curve III (interrupted line - - - - - -) shows the changes three weeks later. All are a little lessened, but in the same direction. Javal 80° $\pm$ 1.0. V L = $\frac{6}{12}\frac{+0.5\text{ sph}}{-1.0\text{ cyl}}$ | = $\frac{6}{9}$. All these changes are comparatively small owing to the peripheral position of the incision. Very much more marked are the changes after a corneal incision, as shown in Fig 2.

CASE 2. *Myopia summa*.—The patient was a man, aged 38 years. Javal R — $\pm$ 0.5. V R < $\frac{6}{60}$ − 24.0 sph = $\frac{6}{24}$. Fig 2. Curve I (continuous line) before operation. Discissio lentis, puncture in the horizontal meridian in the temporal part of the limbus corneæ. Extractio cataractæ linearis 10 days later, a vertical incision from three to four millimetres long in the temporal half of the horizontal meridian two millimetres from the limbus. Curve II (dotted line). recorded seven and a half weeks after first operation. We notice the same changes—i.e., diminution of refraction in the meridian of the incision (horizontal), especially marked in the temporal half of the curve (the one nearest to the incision); increase of refraction in the vertical meridian. The changes were undoubtedly more marked shortly after the operation, but the diagram could not be taken until the cataract was sufficiently absorbed to enable the patient to fixate correctly. Javal: 20° ± 3 5. V.R. = $\frac{6}{18}\,\frac{+\,1{\cdot}5\text{ sph.}}{-\,2\;5\text{ cyl. }20^\circ} = \frac{6}{12}$.

It is well known that by far the greater part of astigmatism is under normal conditions due to faulty curvature of the cornea. Astigmatism caused by irregular contraction of the ciliary muscle has never been proved.[8] Any plan, however, to cure astigmatism by perforating corneal incisions based on experience gained by other operations seems to me to be wholly unjustifiable on account of the danger involved with any perforating wound. Incidental experiences when cauterising a corneal ulcer or infiltration induced me to try galvano-caustic. I employed the ordinary loop of fine platinum wire, presenting at its tip a surface of about one millimetre. The instrument is connected with the electric main (alternating current) by a transformer and a rheostat. Dull red heat was employed. A small punctiform burn was effected in the limbus or in the cornea, penetrating to about one-half of the corneal thickness. The small operation was performed under local (cocaine—holocaine) anæsthesia. In some cases I found it advisable to mark the point chosen for cauterisation by a small superficial abrasion and subsequent staining with fluorescin. The marking was done while the patient looked at a distant (five metres) object straight in front of him in the horizontal plane, so as to obviate torsion movement of the eyeball. The cauterisation itself lasted from two to three seconds. The effect was in all cases exactly the reverse of what took place by incision. The following case will illustrate this.

CASE 3. *Hypermetropic astigmatism.*—The patient was a girl, aged nine years. Javal: R. 170° ± 3·5. Retinoscopy: $\lfloor^{0}_{\,+4{\cdot}0}$ V.R. = $_{24}$ + 3·5 cyl. | = $\frac{6}{12}$. Continuous curve I before operation. A punctiform cauterisation was made in the horizontal meridian at two places about one and a half millimetres distant from the outer and the inner limbus respectively. The immediate result as measured by the ophthalmometer was R. | ± 2·0. The treatment consisted of instillations of homatropin, bathing the eye with warm boric acid lotion, and a monocular bandage for two days. Two days after the operation the dotted Curve II was taken (Fig. 3). Javal: R. | ± 1·5. It will be seen that the horizontal meridian shows a considerable increase of refraction, the vertical one showing a diminution of lesser extent. The changes are exactly the reverse of those after corneal incision. Four days after the operation the condition was—Javal: R. 170° ± 0·5. Retinoscopy: $\lfloor^{+1{\cdot}5}_{\,+\,1\,5}$. Eight days after the operation—Javal: R. 170° ± 0·75. V.R. = $\frac{6}{12}$ + 1·25 = $\frac{6}{9}$. Six weeks after operation—Javal: R. — ± 1·5. Retinoscopy: $\lfloor^{+1{\cdot}0}_{\,+\,2\,0}$. As in incisions the immediate effect decreases after a short time, but a permanent result is always left. The immediate effects of the operation as well as its decrease afterwards are, however, very much greater than in the case of incisions. It will be noticed later that this decrease is not so marked in adults. Owing to the great increase in refraction of the operated meridian and the slight decrease of the one perpendicular to it, the eye becomes necessarily more myopic—i.e., less hypermetropic. The left eye of the same patient presents changes very similar after the operation. Javal: L. — ± 3 75. Retinoscopy: L. $\lfloor^{0}_{\,+4{\cdot}0}$ V.L. = $\frac{6}{24}$ + 3·5 cyl. | + $\frac{6}{12}$. Operation as in the right eye—i.e., punctiform cauterisation of the cornea at both ends of the horizontal meridian about one and a half millimetres from the limbus. Immediate effect: L. ± 1·5. Two days after the operation: L | ± 0 5. Six days after operation: L — ± 0 5. Retinoscopy: $\lfloor^{+2{\cdot}0}_{\,+2\,0}$ V.L. = $\frac{6}{12}$ + 1·5 = $\frac{6}{9}$. Six weeks after operation: L. — ± 1 25. Regrettable is here again the partial loss of the first operative result. However, the little girl, who before the operation was obliged to wear glasses always, uses them now for near work only. Another slight cauterisation performed three months later has removed the remaining astigmatism and the refraction of both eyes is now + 2 0 D. sph. $\left.\begin{array}{l}\text{V. R.}\\ \text{V. L.}\end{array}\right\} = \frac{6}{9} + 1{\cdot}5 = \frac{6}{6}$.

CASE 4. *Mixed astigmatism.*—Curve I, Fig. 4, before operation. Javal: R. — ± 3·5. Retinoscopy: R. $\lfloor^{-\,2{\cdot}0}_{\,+\,1{\cdot}0}$ V.R. = $\frac{6}{36}\,\frac{+\,1{\cdot}0\text{ sph.}}{-3\;0\text{ cyl.}\,-} = \frac{6}{12}$. The patient, aged 42 years, complained of neuralgic pains over the eyebrows, especially when she left off her glasses. Punctiform cauterisation at both ends of the horizontal meridian of the cornea one millimetre distant from the inner and outer limbus was performed, the cauterisation wound in the temporal half of the cornea being rather deeper. The immediate result was R. | ± 1 0. On the day after operation: R. — ± 0·5. Three days after operation: R. 170° ± 1·0. Curve II taken. The increase in the refraction of the horizontal meridian was very much more marked in its temporal half (the right half of Curve II) simply because the cauterisation in that part of the cornea extended deeper into the tissue (Fig. 4). Six days after operation: R. 170° ± 1·0. Retinoscopy: R. $\lfloor^{-\,1{\cdot}0}_{\,-\,0{\cdot}5}$. V.R. = $\frac{6}{12}\,\frac{+\,0\;5\text{ sph.}}{-\,0\;5\text{ cyl. }-} < \frac{6}{6}$. Ten weeks after operation: R. 170° ± 1·5. V.R. < $\frac{6}{12}$ - 0 75 cyl. axis 170° = $\frac{6}{9}$. Three months after operation: R — ± 1·5 V.R. = $\frac{6}{12}$ — 1·0 cyl. axis — = $\frac{6}{9}$. Left eye of the same patient—Javal: 10° ± 2 5. Retinoscopy: $\lfloor^{-\,1{\cdot}0}_{\,+1{\cdot}0}$ V.L = $\frac{6}{12}\,\frac{+\,0\;75\text{ sph.}}{-\,1{\cdot}5\text{ cyl. }-} = \frac{6}{6}$. Curve I, Fig. 5, before operation. Operation as in right eye. Immediate result: L. | ± 1 5 Three days after operation: L. ± 0 25. Curve II taken It is rather difficult to make the cauterisation wound on both sides perfectly equal and we see here again a considerable difference in the increase of refraction between the two sides of Curve II. Eight days after operation: L. — ± 0·5. Retinoscopy: L. $\lfloor^{0}_{\,0}$. V.L. = $\frac{6}{6}$. One month after operation: *status idem*. Ten weeks after operation: L. — ± 0 75. Retinoscopy: L. $\lfloor^{0}_{\,0}$. V.L. = $\frac{6}{6}$. Four months after operation: L. — ± 1 0. V.L. = $\frac{6}{6}$ — 0·5 cyl. — = $\frac{6}{6}$. The patient goes about without glasses with comfort.

CASE 5. *Compound hypermetropic astigmatism.*—The patient, about 30 years of age, complained of neuralgic pain in the right eye. Javal: R. ± 0. Retinoscopy: R. $\lfloor^{+2\,5}_{\,+\,0\,5}$. V.R. = $\frac{6}{36}\,\frac{+\,2\;0\text{ sph.}}{-\,2{\cdot}0\text{ cyl. }|} = \frac{6}{18}$. Left eye normal. Emmetropic. V.L. = $\frac{6}{6}$ Punctiform cauterisation of the right cornea in the upper part of the vertical meridian, one and a half millimetres from the limbus. Three days after operation—Javal: R. — ± 2·5. Retinoscopy: R. $\lfloor^{+1\,5}_{\,+1\,5}$. V.R. = $\frac{6}{6}$ + 1 0 = $\frac{6}{6}$. Curve II taken. This was one of the rare cases in which the astigmatism was not due to abnormal curvature of the cornea. Although there was no corneal astigmatism before the operation examination by the direct method, by retinoscopy as well as by test-types, proved an astigmatism of 2 D. to be present. There was no subluxation of lens (Fig. 6). The operation decreased the curvature of the horizontal meridian, increasing it in the vertical; and we find afterwards corneal astigmatism 2 5D; total astigmatism, none. I have not seen the pa[illegible]ient since, as she left Europe. I heard, however, from her [illegible] three months after the operation that the right eye was the[illegible]n quite comfortable and that she could see much better with it than she could before the operation.

CASE 6.—*Myopic astigmatism.*—The patient was a woman, aged about 30 years. Both eyes Javal: — ± 1·5. Retinoscopy: $\lfloor^{-\,1\,0}_{\,0}$. V. = $\frac{6}{12}$ - 1·0 cyl. — < $\frac{6}{6}$. Fig. 7 repr[illegible]esents the right eye. Both corneæ were cauterised at one [illegible] only in the horizontal meridian one millimetre from the tem[illegible]al limbus. As before, the corneal curvature (refraction) [illegible]

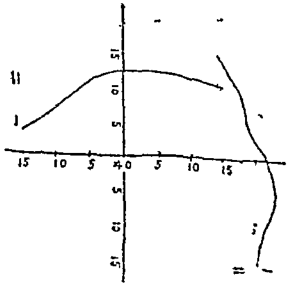

FIG 8

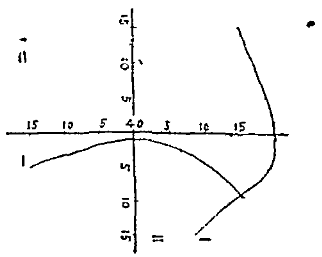


meridian operated upon, decreasing in the other. Immediate result: R | ± 1 5. L | + 2 0. A fortnight later: R. — ± 0·5. R. $\big\lfloor^{-0\cdot5}_{\quad-0\,5}$. V.R. < $\frac{6}{6}$ − 0·25 = $\frac{6}{6}$. L. ± 0. L. $\big\lfloor^{-0\,5}_{\quad-1\,0}$. V.L. = $\frac{6}{9}$ — 0 5 cyl. | = $\frac{6}{6}$. A month after the operation both eyes were about equal. Refraction — 0 5 D. sph. The patient is quite comfortable without any glasses.

CASE 7. *Mixed astigmatism; axis oblique.*—The patient was a man, aged 60 years. Right eye normal. L. 30° ± 4·5. V.L. = $\frac{6}{36}$ $\frac{+\,3\,0\text{ sph.}}{-4\cdot0\text{ cyl. }30^\circ}$ < $\frac{6}{12}$. Fig. 8, Curve I, before operation. Punctiform cauterisation of the cornea at both ends of 30° meridian, two millimetres from the limbus. Immediate result: L 110° ± 2 5. Three days later: L. 110° ± 1·5. Curve II taken. Three weeks later: L. 35° ± 0 5. V.L. = $\frac{6}{12}$ + 1 0 = $\frac{6}{9}$.

Ten other cases operated upon by me in the same manner showed very similar results. The cauterisation wound invariably healed in from one to two days. About three weeks after the operation the scar could be detected only by a very close inspection or by focal illumination. I selected only those cases for operation in which there was a reasonable chance that the patient could do without glasses afterwards. Therefore the operation is limited to cases of compound hypermetropic and mixed astigmatisms. The best results are obtained in the former cases, the patients losing their astigmatism and becoming less hypermetropic or emmetropic. It is always necessary to produce a considerable over-effect, as a considerable part of the first result disappears in time. The part which is lost seems to be greater in children than in adults. Further, the more superficial and peripheral the cauterisation the more likely is the result to disappear in time. If, however, the cauterisation extends through about one-half of the corneal thickness a permanent result will be obtained. I may mention that in some cases the result was perfect eight months after the operation. It stands to reason, however, that a longer observation—a careful discrimination as to the patient's age, sex, and state of health—would add much greater verification and value to the suggestions made above. I feel, however, justified in advising the operation for cases of compound hypermetropic astigmatism of considerable degree. Under those conditions the patient is, at any rate, sure to lose a good deal of his astigmatism and hypermetropia so as to enable him in most cases to dispense with the constant wearing of glasses. With ordinary precautions there is no risk attached to the operation.

Finsbury-circus, E C.

A FURTHER NOTE ON

THE TECHNIQUE OF THE QUANTITATIVE ESTIMATION OF THE BACTERICIDAL POWER OF THE BLOOD,

AND (INCIDENTALLY) ON THE POSSIBLE APPLICATION OF SUCH ESTIMATIONS TO THE STANDARDISATION OF BACTERIAL VACCINES.

BY A. E. WRIGHT, M.D. DUB.,
PROFESSOR OF PATHOLOGY, ARMY MEDICAL SCHOOL, NETLEY.

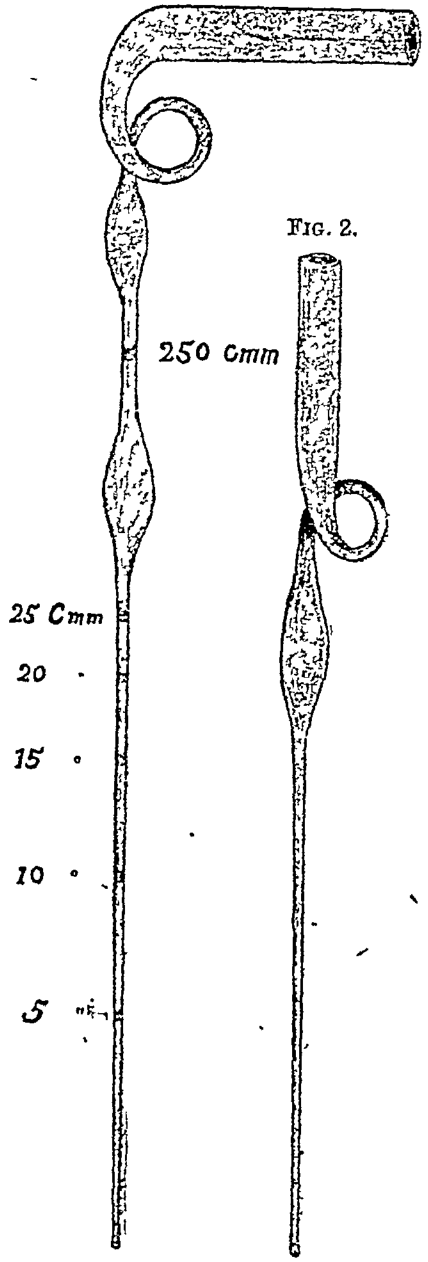
THIRD COMMUNICATION.[1]

IN my last communication I described a method by which the bactericidal power of the blood could be quantitatively determined. The procedure in question consisted essentially of three operations. In the first a series of minimal volumes of serum were mixed with a series of graduated dilutions of a broth culture, in each case in a capillary tube. In the second operation, the survival or destruction of the bacteria was tested after they had been in contact with the serum for any desired period by blowing out the contents of the tube, either into sterile broth or on to the surface of agar. In the third operation the number of the bacteria present in the culture employed for the determination of the bactericidal power was elicited by mixing in a capillary tube a measured volume of diluted broth culture with an appropriate volume of gelatin, and by counting the colonies which developed.

In the course of further daily occupation of the question of the quantitative estimation of the bactericidal power of the blood I have been able to introduce certain simplifications into the methods. The first of the modifications in question consists in substituting the spiral of glass shown in Fig. 2 for the cotton-wool plug previously employed for protecting the interior of the tube against contamination. The moulding of this spiral involves practically no additional labour. The time occupied in plugging the tubes with cotton-wool and sterilising them in the flame is thus saved, while the interior of the tube is quite as effectively guarded against contamination as is the case when the cotton-wool plug is employed.

FIG. 1.

FIG. 2.



The method of determining whether bacteria have or have not survived their contact with the serum has been simplified as follows. After the bacteria have been in contact with the serum for the desired period sterile broth is introduced into the tube in sufficient quantity to fill up the mixing chamber. This done, the tube itself is employed as a cultivation tube. The manipulations required for the purpose of filling up the tube with broth are of a nature which will present no difficulty to those who have familiarised themselves with the technique previously described by me in connexion with the filling in of sedimentation tubes. These operations are as follows.

---

[1] The first communication was published in THE LANCET of Dec. 1st, 1900, p. 1556 and the second communication in THE LANCET of March 2nd, 1901, p. 609.

The tubes which contain the mixture of serum and bacterial culture having been taken in hand *seriatim*, a rubber teat is in each case fitted in a collapsed condition upon the upper end of the tube. The lower end of the tube—i. e., the terminal bead and a small portion of the capillary stem beyond this—is now introduced into a flame (a small luminous flame, such as that of a "peep light," may conveniently be employed for the purpose), and this end is, whilst still hot, plunged into a watch-glass containing sterile broth. The end having been snapped off in this manner, the nutrient broth runs up into the tube and is allowed to fill in the mixing chamber nearly to the top. The tube is then removed from the fluid—the inflow being at this moment stopped by making a gentle pressure on the teat—and the end is sealed up in the flame. A decision as to whether the bacteria have or have not survived the action of the serum can now, after the tube has been cultivated for 24 hours at blood temperature, be judged of by a mere inspection Where the determination of bactericidal power has been instituted with an agglutinating serum, care will of course have to be taken not to overlook the sedimented bacteria which may be lying at the bottom of the tube. In cases of doubt the contents of the tube can always be microscopically examined.

The method of determining the number of bacteria present in the culture employed has also been simplified in the following way. A series of measured volumes of an extreme dilution of the culture is now taken for cultivation, the number of the contained bacteria being determined by ascertaining what volume of the diluted broth culture has to be employed to obtain a cultivation.

For the purposes in question it is obviously necessary to be able to dilute quickly and unlaboriously. The pipette represented in the figure enables this to be done. The pipette in question is made as follows. 1. A piece of stoutish glass tubing (of about three eighths of an inch in diameter) is drawn out in the flame into a capillary stem. 2. This capillary stem is then graduated in five divisions of five cubic millimetres by the method fully described in a previous communication. 3. 10 successive volumes of coloured fluid, each consisting of 25 cubic millimetres, are filled into the pipette, a bubble of air being, as in the technique already described in connexion with capillary sedimentation tubes, interposed between each two of the 25 cubic millimetre volumes last spoken of. 4. A division mark is now placed on the body of the tube, corresponding to the 250 cubic millimetres now filled in. 5. The contents having been blown out and the tube having been dried, the tube is now drawn out in the flame at the point indicated. After cooling down the pipette and filling it in again with 250 cubic millimetres, the division mark will now be found to fall on some part of the narrow, drawn out portion of the stem. This point, when found by same procedure as before, is to be indicated with a division mark. 6. The tube is then to be drawn out again a little above this point so as to form a safety chamber, the narrowed part of the tube above this being moulded into a stout spiral. With reasonable care and with an occasional refreshing of the division marks the diluting pipette which has thus been made may be employed for an indefinite period.

To come, however, to the particular application of the pipette to the estimation of the number of bacteria contained in the culture employed for the bactericidal estimation, the first step will be to place in front of one's self four sterile watch glasses and to cover each of these in. By filling in the pipette twice, and by withholding, when expelling the contents of the pipette into the watch-glass, one five cubic millimetre volume, 495 cubic millimetres of sterile broth are introduced into the first watch-glass. In a similar manner the two next watch-glasses are filled in each with 495 cubic millimetres. Lastly, the fourth watch-glass is filled in with 990 cubic millimetres. Five cubic millimetres of the undiluted bacterial culture are then introduced into the first watch glass by means of the graduated pipette. After carefully mixing, five cubic millimetres are carried on from this into the second watch-glass Before proceeding to mix the contents of the second watch-glass the pipette is now carefully washed out in boiling sterile water. Mixture having been effected five cubic millimetres are then carried on from the second to the third watch-glass. Lastly, the same precautions having been taken as in the previous case, 10 cubic millimetres are carried forward into the fourth watch-glass and mixture is effected. In this manner a dilution of 100,000,000 will have been arrived at in the case of the last watch-glass, and this, in the case of the typhoid cultures which have been employed by me, represents an appropriate dilution.

The next step in the procedure is to take a series of measured volumes of the 100,000,000 dilution. This is done by means of the graduated pipette already employed. Convenient volumes to employ are volumes of 500, 250, 125, 50, 25, 10, and five cubic millimetres respectively. These are measured off directly into tubes of sterile nutrient broth or, in case of the smaller volumes, on to sterile nutrient agar. The first and second of these volumes are conveniently obtained by filling in the pipette in the first case twice and in the second case once; the volume of 125 cubic millimetres is obtained by filling in the pipette five times successively up to the 25 cubic millimetres division-mark, a bubble of air being, of course, interposed between each two volumes. The fourth and fifth measured portions, consisting as they do of 50 and 25 cubic millimetres respectively, will conveniently be obtained by filling in the pipette in the first case twice and in the second case once up to the 25 cubic millimetre division-mark. Lastly, the sixth and seventh volumes are conveniently obtained by filling in the pipette again to the 25 cubic millimetre division and expelling from the pipette in the one case two volumes and in the other case one volume of the five volumes of contained fluid.

The method of calculating the results will best be explained by the assistance of two actual examples of enumerations of the number of bacteria obtained in the typhoid cultures.

EXAMPLE 1.

Tube 1, to which have been added 500 cubic millimetres of 100 000,000 dilution	Growth.
Tube 2, to which have been added 250 cubic millimetres of 100,000,000 dilution	Sterile.
Tube 3, to which have been added 125 cubic millimetres of 100,000 000 dilution	"
Tube 4, to which have been added 50 cubic millimetres of 100,000,000 dilution	"
Tube 5, to which have been added 25 cubic millimetres of 100,000,000 dilution	"
Tube 6, to which have been added 10 cubic millimetres of 100 000,000 dilution	"
Tube 7, to which have been added 5 cubic millimetres of 100,000,000 dilution	"

Taking these tubes *seriatim*, the inferences that can be drawn from their consideration are as follows.

Tube 1.—From the fact that a culture of typhoid bacillus is obtained in the case of this tube which contained half a cubic centimetre of the diluted culture it may be inferred that one cubic centimetre of the diluted culture in question contains two or more typhoid bacilli.

Tube 2.—From the fact that this tube which contained one quarter of a cubic centimetre of the diluted culture remains sterile, it may be inferred that one cubic centimetre of diluted culture contains less than four typhoid bacilli. Or, if we take into consideration the fact that no culture develops in Tubes 3, 4, 5, 6, and 7, which contain in the aggregate 465 cubic millimetres, it may be inferred that less than 2·1 (1,000 ÷ 465 = 2·1) are contained in one cubic centimetre of the dilution employed. Taking, therefore, 2 as representing the number of bacteria in one cubic centimetre of the dilution employed, and multiplying this figure by 100,000,000, we arrive at 200,000,000 as the number of typhoid bacilli contained in one cubic centimetre of the original culture.

EXAMPLE 2.

Tube 1, to which have been added 500 cubic millimetres of 100,000 000 dilution	Growth.
Tube 2, to which have been added 200 cubic millimetres of 100,000,000 dilution	Sterile.
Tube 3, to which have been added 100 cubic millimetres of 100,000,000 dilution	Growth.
Tube 4, to which have been added 50 cubic millimetres of 100,000 000 dilution	Sterile.
Tube 5, to which have been added 25 cubic millimetres of 100,000,000 dilution	"
Tube 6, to which have been added 10 cubic millimetres of 100,000,000 dilution	"

We may infer here as before from the fact that a growth takes place in Tube 1 that one cubic centimetre of the dilution employed contains at least two bacilli. From the results of Tube 2, which has been filled in with one-fifth of a cubic centimetre of the diluted culture, we infer that there are less than five bacilli in the cubic centimetre of dilution.

get a lotion for the "whites," but for which I declined to give a prescription without seeing the patient first. I then elicited that they were sometimes tinged and that she had a good deal of pain and some hæmorrhage on coitus. On examination about two inches within the vagina a cauliflower growth of about the size of three walnuts with a base of the size of a florin was met with. With a finger in the rectum and one in the vagina no trace of thickening could be felt around the clearly circumscribed base and the bowel-wall was freely moveable away from the base. Beyond the growth the vagina was perfectly healthy as was the cervix. Several glands in both groins were enlarged and tender. Owing to the total absence of any infiltration of the vagina I thought that the case was probably a papilloma and that the enlargement of the glands was simply due to the irritation of the growth and the secretion. I sent the patient to University College Hospital where Dr. G. F. Blacker removed the growth by a circular incision of about the size of a crown-piece, this seeming to be well beyond the growth in all directions. The glands were removed at the same time. The patient left the hospital in about three weeks and on examination later I found a great deal of cicatricial contraction with hardened masses bulging between the scars and bleeding freely on the slightest touch. In less than a month there were large warty growths over the vulva and others at the surface of the vagina which in later times have become as large as oranges, giving great difficulty in micturition, while the site of the vaginal growth has spread and invaded the bowel to such an extent as to threaten obstruction of the bowels, this only being obviated by passing a large catheter through the mass and keeping the fæces very liquid by numerous small injections through it. The patient has now numberless disseminated nodules over the skin of the abdomen with affections of some of the glands in the groin.

In a recent letter from Dr. Blacker he tells me that the growth proved microscopically to be carcinoma. Except when the bowels have a difficulty in being relieved the pain is kept down perfectly effectually by repeated doses of nepenthe which, in this case, as in many other cases, seems most effectual in allaying pain without producing any disorder of the head, stomach, or bowels and is in this way immeasurably superior to the tincture of opium of the British Pharmacopœia

One moral to be gained from this case is not to prescribe without a full examination of the patient. Had I given a prescription (which would naturally have failed) and then had seen the patient some weeks later my conscience would have reproached me for ever with the thought that had its cause been known earlier it would have been probably a curable case—an erroneous conclusion, but one which would never have been disproved.

King Henry's-road, N.W.

> Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Procœmium.

ST. BARTHOLOMEW'S HOSPITAL.

A CASE OF STRANGULATED HERNIA IN A PREMATURE CHILD, AGED FIVE WEEKS; OPERATION; RECOVERY.

(Under the care of Mr. D'ARCY POWER)

STRANGULATED hernia in very young children is extremely rare, for though about 100 cases of herniotomy for strangulation have been recorded up to the present in which the patient was under a year old, this number is seen to be small when compared with the very large number of children who suffer from congenital inguinal hernia Contrary to what might have been expected, the mortality is by no means high in those cases in which an operation is performed. About 16 cases have been recorded during the first month and about as many in the second.[1] Nearly half the cases in children under one year occur during the first three months.

On April 15th, 1901, a very wasted and ill-nourished male child, aged five weeks, was admitted into St. Bartholomew's Hospital, under the care of Mr. D'Arcy Power, with the history that a swelling was first noticed in the left groin on the 12th and that on the 13th the child vomited every time he was put to the breast and cried all day. The vomiting continued till the time of admission and the bowels had not been opened since the 12th at 9 A.M. The child was said to be born prematurely at seven months. He was blue and collapsed and in the left inguinal region there was a hernial swelling as large as a walnut. The hernia was cut down upon as taxis under chloroform failed to reduce it. The sac was opened and was found to contain a very little piece of omentum with a knuckle of small intestine rather deeply congested. The hernia was of the congenital variety and there was practically no fluid in the sac. The constriction was situated at the internal ring and was very tight. The stricture was divided, the bowel was returned, and the sac was isolated, ligatured in two places and divided, the distal part being left to form a tunica vaginalis whilst the proximal portion was stitched to the peritoneal surface of the abdominal wall. The external abdominal ring was closed with a single suture and the wound was united with silkworm gut. The child bore the operation well and was fed by the mouth four hours after he recovered from the anæsthetic. The bowels were opened on the following morning and he never vomited. The sutures were taken out on the fourth day when the wound was perfectly healed. A collodion dressing was applied and the child left the hospital on the 30th. He weighed 4 pounds 12 ounces on admission and 5 pounds 1 ounce on the day of discharge

On May 21st the child was taken to Mr. Power, as a new patient, at the Metropolitan Dispensary for the relief of a hernia on the right side. He recognised the child as soon as he saw the scar and as the hernia seemed to be due to the straining caused by a very tight phimosis a circumcision was performed. The child again recovered with a single dressing.

Remarks by MR. POWER.—Cases of strangulated hernia requiring an operation are sufficiently rare in very young children to make it worth while to record their appearance from time to time. I am indebted to Mr. C. S Hawes, my late house surgeon, for the notes of the case.

ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

A CASE OF CÆSAREAN SECTION AND COMPLETE REMOVAL OF THE UTERUS IN THE EIGHTH MONTH OF PREGNANCY FOR CANCER OF THE CERVIX.

(Under the care of Dr. THOMAS OLIVER and Mr. RUTHERFORD MORISON.)

THE best treatment for malignant disease of the cervix of an unimpregnated uterus is total hysterectomy, and the coexistence of pregnancy with the malignant disease increases the advisability of immediate operation, especially in cases in which there is a good hope of removing completely all the new growth. When pregnancy has advanced so far as the eighth month Cæsarean section followed by hysterectomy is the only satisfactory method of dealing with the condition. In the case recorded below there is very good reason for hoping that no recurrence will occur.

On Jan. 25th, 1901, a married woman, aged 39 years, was sent by Mr. H. B. Ord of South Shields to consult Dr. Oliver on account of uterine hæmorrhage. She was then far advanced in pregnancy. She looked a healthy but anæmic woman and was the mother of nine children, the youngest of whom was two years and one month old. All her confinements had been easy. Since the birth of her last child the patient had suffered on a few occasions from uterine hæmorrhage, especially during the last 18 months. Blood would come away once or twice a week and would continue only a few hours or for the greater part of a day. The hæmorrhage was irregular and for five or six weeks might entirely disappear. Five months before she had a severe but painless bleeding. This continued for two hours and then suddenly ceased. Half a pint of bright, clotted blood escaped in a very short time. No more blood was seen by the patient until three days before seeing Dr. Oliver when there was another excessive loss unaccompanied by pain, but so profuse as to cause considerable anxiety to her medical attendant and friends. Seven months previously she first knew she was pregnant. There was morning sickness and in due course she "quickened," the abdomen meanwhile becoming correspondingly enlarged. When examined in Newcastle the movements of the child were very active. Apart from the hæmorrhages above alluded to there had been no vaginal discharge. The blood that escaped had no fœtor. The patient's general health had remained good. Her lips were slightly cyanosed. As regards the heart, over the tricuspid area a soft systolic murmur could be heard. The lungs and kidneys were healthy. The uterus reached to within three inches of the ensiform cartilage. The fœtus was easily felt, its movements were extremly active, and its heart's sounds could be best heard just above the umbilicus, and the placental souffle close to the umbilicus on the left side. On vaginal examination Dr. Oliver found the os uteri open and the interior rough and irregular; the greater part of the cervix uteri, especially on the left side, was occupied by a mass of friable growth the margins of which were irregular, nodular, and disposed to bleed. The cervix felt on the whole fairly moveable and the fornices so far as the finger could ascertain seemed to be free. Through the speculum the growth, which could be seen projecting towards the vagina, was dirty-greyish on the surface and had all the appearance of a cauliflower excrescence.

---

[1] B G. A. Moynihan, THE LANCET, Sept. 25th, 1897, p 788.

Dr. Oliver was therefore confronted with this problem: a woman in the eighth month of pregnancy with cancer of the cervix and the subject of severe recurrent uterine hæmorrhage. What was the best thing to do? To allow the patient to go on to term, to run the risks to herself and child incurred by recurrent excessive hæmorrhage and the dangers incidental to parturition by the passage of the infant through an unhealthy, unyielding, and tearable cervix, or to recommend the bolder, and, as events subsequently showed, the safer, procedure of abdominal section, incision of the uterus, and removal of the child followed by complete extirpation of the uterus and cervix? He advised the latter and recommended Mr. Ord to allow the patient, on account of the serious nature of the operation, to enter the Newcastle Infirmary. Here she was seen by Mr. Rutherford Morison and as his opinion both as regards the diagnosis and line of treatment was similar to that which has just been expressed the patient was placed under his care.

Operation was performed by Mr. Morison on Jan. 31st, 1901. Chloroform was the anæsthetic used. The patient was placed in the Trendelenberg position and kept thus throughout. After disinfecting the skin of the abdomen and vagina as far as possible an incision was made commencing three inches above the umbilicus and carried to the pubes; the uterus was turned out and the abdominal cavity was packed off with sponges. The infundibulo-pelvic ligaments on either side were ligatured and divided along with the lateral portions of the broad ligaments. The uterine arteries were held between the fingers and thumb of an assistant. The womb was opened by a vertical incision from the fundus downwards and the child was extracted. The placenta was observed lying to the left and posterior part of the fundus. An elastic ligature was tied round the uterus just above the cervix and the upper segment was cut away. There was very little bleeding at this stage of the operation The placenta was not removed. The broad ligaments were next cut through and the uterine arteries were clamped and cut. These vessels were unusually large and their cervical branches bled freely. Many large veins had to be clamped and tied An attempt to remove the diseased cervix by the vagina was not persisted in and it was removed from above All the disease seemed to be eradicated, for, so far as could be seen, the broad ligaments and peri-uterine tissues did not appear to be infiltrated. The extra-peritoneal part of the pelvis was packed with antiseptic gauze and part of this was brought down into the vagina. The peritoneum was sutured with continuous catgut over the stumps of the broad ligaments and the gauze, thus completely closing the pelvic peritoneum. The abdominal wall was completely sutured in layers with catgut The patient stood the operation well. The infant was a healthy female of eight months. On removal from the uterus she was cyanosed and did not breathe, but under the attention of Dr. W. Simpson, senior house physician, life was soon restored. The operation lasted one hour and 50 minutes. Both ovaries were removed along with the womb.

For the first few days after the operation the patient progressed very satisfactorily. Beyond occasional sickness all seemed to be going on well until Feb. 11th, when on dressing the abdominal wound it was noticed that while the lower part of the wound had perfectly healed a loop of small intestine about six inches in length was seen protruding through the upper part of the incision; it was reddened and bled easily and on its surface a few flakes of lymph were noticed. The bowels had been freely moved—rather purged than otherwise, the stools being offensive. The exposed gut was washed with boric lotion; the omentum was found adherent to the edges of the incision; this was separated and returned along with the intestine into the adbominal cavity and the incision was closed with through and-through silkworm-gut sutures. The progress after this continued to be satisfactory for a period. On March 18th a small vesico-vaginal fistula was detected but it gave the patient very little trouble. The abdominal incision had practically healed. Both the mother and the child were remarkably well and were leaving the infirmary that day. Mr. Gray Turner, surgical registrar, who examined the cervix microscopically, reported: "Epithelioma; quite characteristic." On May 6th Mr. Turner wrote to Dr. Oliver: "Mrs. —— was at the infirmary to-day. She looks well and strong; the abdominal incision is sound. The vesico-vaginal fistula is healed and there is no sign of recurrence. The baby is flourishing."

Remarks by Dr OLIVER.—There are few things more distressing to a medical practitioner than for him to find one of his patients who is the mother of a large family the subject of cancer of the uterus and approaching the end of pregnancy. The detection of cancer of the neck of the uterus in the first two or three months of pregnancy is a much less formidable matter, especially if the disease is limited to the cervix, and in most of these cases it will be limited, for were it at all advanced the foul discharges would of themselves be sufficient to prevent conception taking place. In such a case, with malignant disease limited to the cervix, there is no need to delay operation. Total extirpation of the uterus by the vagina is at once called for. But when pregnancy is far advanced the case is quite different. There is a temptation to allow the pregnancy to go to term and for the practitioner to buoy himself up with the hope that by application of the forceps or by turning the dangers that are incidental to a tedious labour may be averted, and when the confinement is over that the diseased uterus can then be dealt with. But is there any ordinary certainty that the life of the mother will be spared to term and that her child will then be still alive? Too often the hæmorrhages are so profuse that the mother becomes exhausted or she becomes poisoned by absorption of her discharges. There are few obstetricians who will deny that carcinoma advances in a pregnant uterus much more rapidly than in an unimpregnated uterus. By allowing the pregnancy to run its course and the disease to make further progress we make labour more difficult owing to the unyielding tissues of the cervix and more dangerous to the mother in consequence of the friable nature of malignant structures, their tendency to tear, and for the rupture to extend into the uterus and to cause death by shock and hæmorrhage Of 180 cases of carcinoma of the uterus in pregnant women collected by Herman in 11 the uterus ruptured Cohnstein has reported 14 cases in which women died undelivered, 13 being at full time and 1 in the seventh month of pregnancy Although in the later stages of pregnancy Cæsarean section with abdominal hysterectomy is a line of treatment to be carefully considered in these cases, it is only right to mention that surgeons have removed the uterus per vaginam as late as the seventh month of pregnancy. I am in favour of the abdominal method and also of not allowing the pregnancy to go to term. The case which we have reported was fortunately one in which, although the cervix was much destroyed by cancer, the fornices were clear. The successful result shows that for this case at any rate the proper treatment was adopted.

AT the Bedwellty (Mon.) School Board election held on May 20th, Mr. Howell Thomas Evans, M.R.C.S. Eng., L.A.H. Dub., D.P.H. Cantab., J.P., was returned at the head of the 13 successful candidates.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Traumatic Subdural Hæmorrhage successfully treated by Operation.—Extreme Dilatation of the Left Auricle of the Heart.—Acute Suppuration of the Thyroid Gland Complicating Typhoid Fever.—Annual Meeting.

A MEETING of this society was held on May 24th, Sir R. DOUGLAS POWELL, Bart, the President, being in the chair.

Dr. RISIEN RUSSELL and Mr. RAYMOND JOHNSON made a communication upon a case of Traumatic Subdural Hæmorrhage in which convulsions, occurring on the sixth day, were successfully treated by operation. The patient was a man, aged 33 years, who fell down a flight of stone steps. The immediate symptoms were those of concussion and there was a superficial scalp wound in the left parietal region. During the five days which followed the injury there were no noticeable symptoms, but on the sixth day convulsions supervened, which were frequently repeated and involved the left side of the body, spreading across to the right side of the face and right leg, and in some of the most severe fits to the right arm. There was a strong family history of *epilepsy* and the urine contained albumin. In consequence, however, of the distribution of the convulsions, the presence of the extensor response, and of marked left-sided paresis between the fits, the existence of an irritative lesion of the right motor area of the cortex was diagnosed. After the inhalation of chloroform and the administration of chloral and bromide of potassium had failed operation was decided upon. The trephine was applied over the right Rolandic area and several drachms of dark blood were evacuated on incising the dura mater. The surface of the brain presented no unusual appearances beyond very slight bulging. No convulsions occurred after the operation. The paresis of the left side of the body became gradually less and the muscular power became perfect a month after the operation. No satisfactory explanation was offered for the long delay in the incidence of the symptoms. They could hardly be regarded as the result of spreading cerebral œdema because there was no evidence of any laceration of the brain substance.

Dr. ISAMBARD OWEN and Dr. W. J. FENTON communicated a case of Enormous Dilatation of the Left Auricle of the Heart. The capacity of the auricle was 30 ounces; its greatest diameter was six and a quarter inches, exclusive of the appendix, which was also greatly dilated. Its walls were extremely thin but healthy in structure; the pericardium was adherent to the auricle posteriorly. The other cavities of the heart were dilated, but to a more or less extent, the ventricles being also hypertrophied. The mitral orifice admitted four fingers and the edges and cords were somewhat contracted, but no other evidence of former endocarditis was present. The heart and pericardium occupied the entire cavity of the thorax below the level of the fourth ribs in front, the pericardium being adherent to the right parietal pleura from the spine to the anterior axillary line. The diaphragm and liver *were greatly depressed*. The patient, a woman, aged 40 years, was admitted to St. George's Hospital last November with urgent dyspnœa. The apex-beat of the heart was found to be in the eighth space and in the posterior axillary line; a heaving impulse was felt over the front of the chest. *A systolic murmur* and a sharp second sound were heard over the front of the chest, culminating at the apex. A presystolic murmur was also occasionally heard. Loss of vocal fremitus, as well as of percussion resonance and stethoscopic sounds, being found over the right base and flank, paracentesis was performed in the sixth space and mid-axillary line. Pure blood resulted, the trocar having penetrated, as was afterwards found, the left auricle of the heart. The operation was at once suspended. The patient appeared none the worse for the occurrence and survived for three and a half days, dying eventually from asphxyia due to compression of the lungs. On subsequent examination, pulsation, except at the apex, was found limited to the front and part of the flank of the right chest. Over a part of this area was felt a systolic thrill, culminating near the right nipple, where also the systolic murmur had a second culminating point. The patient, it was found, had been in the hospital with cardiac symptoms in 1888 and 1898. On the former occasion the symptoms were stated to be of six years' duration, having begun at the age of 22 years. There had been an attack of rheumatic fever in childhood. On this occasion the condition was not distinguishable from one of mitral stenosis. *On the second* occasion the apex-beat had advanced to the seventh space and mid-axillary line. There were marked pulsation in the lower part of the right side of the chest and a systolic thrill best felt just below the right nipple. A faint thrill was occasionally felt at the apex and a systolic murmur culminated at the apex, the second sound being reduplicated. In the aortic area the first sound was impure and the second was clear. There was no rumble or snap. There was marked pulsation of the lower ribs on the right side, with a systolic thrill most marked just below the right *nipple. Pulsation was seen in the fourth space above* the right nipple. The front and flank of the right chest were dull up to the fourth rib and a loud systolic murmur was well heard over this region. Vocal fremitus was absent from the dull area. The posterior base was resonant, but other pulmonary signs were deficient. The systolic murmur was heard at the angle of the left scapula. The liver was pushed downwards on this occasion and aneurysm was suspected, but no certain diagnosis was arrived at. She had begun to suffer from severe and increasing dyspnœa with pain in the right side of the chest six weeks before her final admission in 1900. Dr. Owen suggested as the first origin of the dilatation of the left auricle the adhesion of the pericardium to its wall. The main difficulty of diagnosis lay in the fact that the possibility of such a condition as existed was not suspected. The possibility being revealed the significance of the physical signs were apparent. As far as he knew the case stood alone, but he proposed to make inquiries as to the existence of similar specimens elsewhere and to lay the results of his inquiries (if any) before the society.—The PRESIDENT remarked on the extreme rarity of the case and asked if any relief ensued from the paracentesis.—Dr. W. EWART remarked that he had seen the patient during life. It was a very rare, if not a unique, condition and it was to him a most interesting one as throwing some light on the mechanism of auricular dilatation in cases of disease of the mitral orifice. In mitral stenosis auricular dilatation was generally attributed to the backward accumulation of blood in the right ventricle. But how was it that in some cases of extreme mitral stenosis there might be hardly any dilatation of the left auricle? The causation of the dilatation was undoubtedly obstruction, but this was situated, he thought, in the present instance, as in many other cases of mitral stenosis, not so much at the mitral as at the aortic orifice. The contracting force of the left ventricle was thus exerted backwards and auricular dilatation ensued.—Dr. SIDNEY COUPLAND thought that in view of the enormous size of the auricle in this case there was another factor in the dilatation—namely, inherent weakness in the auricular wall. The dilatation was, in short, rather of the nature of an aneurysmal one.—Dr. OWEN, in reply, agreed with Dr. Ewart that both the pulsation and the dilatation of the auricle were due to ventricular contraction. The microscope did not reveal degeneration in the muscular tissue of the heart.

Mr. RICKMAN J. GODLEE read a paper on a case of *Acute Suppuration of the Thyroid Gland complicating* Typhoid Fever. The patient was a young woman, aged 20 years, who was attacked with typhoid fever at the end of October, 1900. On Nov. 20th a swelling formed at the lower part of the neck, followed by a patchy irritable rash all over the body which disappeared on the 26th. The swelling, however, rapidly increased in size and her temperature rose, reaching 104 4° F. on the 28th and 105·4° on the 29th, the pulse rising to 140. There had been a moderate degree of swelling in that situation for some years. When first seen by Mr. Godlee the swelling occupied the middle line and extended somewhat to the right but much further to the left. There was difficulty in swallowing and the surrounding structures did not move freely over the swelling. There was no movement of the mass on deglutition. An incision was made in the middle line and a cavity was reached ha[illegible] an inch within the gland, which was of large size. It contained a reddish-brown, sticky fluid, mixed wi[illegible] much friable material. The bleeding was [illegible] alarming. A drainage-tube was inserted [illegible] dressing was applied. The patient was much [illegible] able after the operation. Recovery was [illegible]

March she was restored to perfect health. Mr. Godlee discussed the different varieties of thyroid inflammations: (1) idiopathic with spontaneous subsidence; (2) epidemic, as described by French military surgeons, of the nature of an acute specific fever; and (3) the septic form, of which this case was an example. Acute suppurative thyroiditis had been recorded as occurring in connexion with many infections and septic states, such as rheumatic fever (eight cases), malaria (three cases), typhoid fever (two cases), diphtheria (two cases), erysipelas, pneumonia, ozæna, compound fracture, and erythema nodosum Of 28 recorded cases suppuration occurred in 15, and in six others this point was not mentioned. He suggested that the rheumatic cases ought, perhaps, to be placed in a separate category, as these did not suppurate. It appeared to be especially common in connexion with typhoid fever, and the proper treatment was immediate opening and drainage. There did not appear to be much danger of serious hæmorrhage. The affection was not included among the complications of enteric fever in the current medical text-books, as it ought to be.—Mr. CHARTERS SYMONDS remarked that he had not seen this form of thyroiditis, but he had seen one case of acute thyroiditis accompanied by dyspnœa and swelling which proved to be, when operated on later, a cyst. He had seen one case of gummatous thyroiditis and he had met with a case in which there were several foul abscesses lying around the gland, but so far as he knew they did not lie within the gland.—Sir THOMAS BARLOW recalled the case of a young woman the subject of a small goitre who contracted typhoid fever. The goitre swelled up and tracheotomy was performed, but the patient died. There was no true suppuration—it was a cystic process. He thought that in many of these cases the inflammation took a hæmorrhagic form similar to that which took place in hæmorrhagic pancreatitis.—Mr. GODLEE, in reply, wished to emphasise the fact that in most of these cases the inflammation supervened in a gland already diseased The thyroiditis generally supervened in typhoid fever during the stage of convalescence.

The annual meeting of this society was then held. The report of the council, read by the secretary, showed the society to be in a prosperous condition, the membership now amounting to 610. The treasurer's report was then presented. There was an increase in the expenditure, but only commensurate with the usefulness of the society. Both of these reports were adopted. Various alterations in the rules, as recommended by the council, were passed. Votes of thanks to the President, the Vice-Presidents, and Council, the retiring secretary (Mr. Charters Symonds), and other officers were passed with acclamation. The result of the ballot showed that the officers and council for the ensuing year, [illegible] were duly elected as follows:— [illegible] Marsh. Vice Presidents: Dr. [illegible] n Poore, Dr. W. Joseph Tyson, [illegible] ment Lucas, and Mr. Herbert [illegible] ederick Taylor. Council: Mr. [illegible] Rose Bradford, Dr J. Mitchell [illegible] Dr. J. K. Fowler, Dr. S. H. Habershon, Dr. H. P. Hawkins, Dr. J. A Ormerod, Dr. H. D. Rolleston, Dr. A. F. Voelcker, Mr. Gilbert Barling, Mr. W. H. Battle, Mr. Leonard A. Bidwell, Mr. Stanley Boyd, Mr. L A Dunn, Mr. F. S. Eve, Mr. Raymond Johnson, Mr. John D. Malcolm, Mr. H Betham Robinson, and Mr. Charters J Symonds. Honorary secretaries: Dr. Percy Kidd and Mr. Anthony A. Bowlby.

HARVEIAN SOCIETY OF LONDON.

Congenital Morbus Cordis.—Spastic Paralysis and Friedreich's Disease after Operation.—Cerebellar Ataxy.

A MEETING of this society was held on May 16th, Dr. D. B. LEES, the President being in the chair.

Dr. E. CAUTLEY showed a girl, aged 13 months, with a Loud Systolic Murmur over the Præcordium. The murmur was loudest in the left third interspace near the sternum and was conducted upwards, downwards, and out- ards. It was loud at the apex, in the fifth space in e nipple line, and was heard all over the back of the est, being louder on the left side of the spine There s slight evidence of hypertrophy of the right ventricle. ere was no clubbing of the extremities and neither anosis nor anæmia. The child had no symptoms of heart disease and was well nourished. She was the third living child out of seven. No history of congenital syphilis had been obtained. The murmur had not varied during the nine months the child had been under observation. Dr. Cautley thought there was probably a deficiency in the interventricular septum.

Dr. CAUTLEY also showed a boy, aged 13 years, as a case of Direct Communication between the Aorta and Pulmonary Artery with possibly other deficiency present. The case illustrated the connexion between congenital heart disease and inherited syphilis. He was the eighth child, one of twins, the other being undeveloped. The seventh was stillborn, while the mother was in hospital for syphilitic disease of the throat. The sixth child was healthy up to six years of age and then became blind and imbecile. The patient exhibited other congenital abnormalities—namely, hypospadias and deformity of the toes. He was small for his age, very thin, and had notched, pegged teeth. The heart's apex was in the fifth space, in the nipple line, and there was evidence of some hypertrophy of the right ventricle Over the second and third left interspaces were a double thrill and murmur, chiefly systolic, and corresponding murmurs extending over a fairly wide area. The sounds were clear at the apex. The pulse was 96, small, and soft. There was no clubbing, cyanosis, or anæmia, and the boy had no symptoms of cardiac distress. Dr. Cautley remarked on the d [illegible] cases and thought [illegible] prognosis. He re [illegible] common cause of [illegible] endocarditis.—With reference to the second case Dr. G. A. SUTHERLAND agreed with the diagnosis of congenital disease, probably a communication between the aorta and pulmonary artery. The loud, rumbling, double murmur, in which he thought the diastolic part was much more pronounced than the systolic, the thrill, and the situation of the murmur, all supported this view. The opening was probably a small one, as no great admixture of venous and arterial blood seemed to be present.—The PRESIDENT commented on the difficulty of accurate diagnosis in cases of this kind and thought the explanation given of the murmurs in the present instances was the correct one. He had recently seen a patient with physical signs like those of the second case and post mortem a communication was found between the aorta and pulmonary artery.

Mr. JACKSON CLARKE showed a boy, aged six years, on whom he had operated in April for Severe Spastic Paralysis. All deformity had been removed and the patient could stand alone, and with the aid of an instrument, the structure of which was demonstrated, he already began to walk, and although the gait was somewhat stiff it had none of the previously pronounced spastic features.—Mr. CLARKE, in reply, said that his observations led him to conclude that the benefits obtained in these cases were permanent. If spasm recurred it was within a few weeks of operation, and was merely an indication for a more extensive removal of tendon. In one case where the operation had been done 20 years ago no return of the spastic condition had occurred. In certain cases the relief of the spasm was complete, and after a time the patient could dispense altogether with instruments.—Mr. JACKSON CLARKE also showed a boy, aged nine years, who had suffered from extreme Deformity of the Feet due to Friedreich's Disease. He had never walked well and just previously to operation had ceased to be able to walk at all. To correct the deformity the plantar fascia and short plantar muscles, and on a subsequent occasion the tendo Achillis and the tendons of the long flexors of the toes and those of the tibiales muscles, had been cut. The boy could now walk in comfort and was free from any danger of return of the deformity, and though the progress of the disease could not be arrested the patient would be able to walk about for some years.—Mr. NOBLE SMITH stated that although many cases of severe spastic paralysis were unsuited to operation, there were yet a certain number which could be distinctly benefited by tenotomy. The case shown by Mr. Jackson Clarke exemplified this fact, and he (Mr. Noble Smith) had seen several instances in which children previously unable to walk at all had been enabled by operation to get about in a manner on their feet They must not expect brilliant results in such cases, but they could realise the enormous difference [illegible] t [illegible] e [illegible] in cases after operation, not only in respect to powers of locomotion, but also as regards a lessening of spasm. He also had noticed an improvement in the mental capacity of children whose brains had been affected.—The PRESIDENT and Mr. W. W. CAMPBELL WILLIAMS also took part in the discussion.

Mr. E. R. CLARKE showed (for Dr. H. A. CALEY) a boy, aged 10 years, suffering from Ataxy of a Cerebellar Type. The child was said to have been perfectly well until six weeks before, when, after a slight fall which caused the nose to bleed, marked unsteadiness of gait was noticed. Since that time on attempting to walk there had been a marked tendency to fall backwards, so that no progress could be made. He could not stand with his feet together; with his feet widely apart he could stand with difficulty. On shutting his eyes he invariably fell backwards. Excepting for occasional frontal headache, slight exaggeration of the right knee-jerk, and vomiting on one or two occasions, there had been no other symptoms, and the optic discs had remained normal. Latterly, the ataxy had lessened to some extent. Dr. Caley regarded the symptoms as referable to a lesion of limited extent implicating the middle lobe of the cerebellum; the possibility of a small hæmorrhage of traumatic origin had been considered, but the presence of a new growth or tuberculous mass was considered more probable.—Dr. SUTHERLAND found it difficult to form a definite opinion, but the evidence adduced of cerebellar disease was far from conclusive. The gait as demonstrated was not characteristic of cerebellar or of any other disease, and as muscular power was manifested in the lower limbs through other tests than the walking one he suggested the presence of a functional element in the case which might be amenable to treatment.—The PRESIDENT and Dr. CAUTLEY also commented on the case and suggested that the child should be brought before the society on some other occasion.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Patients and Specimens.

THE eighth meeting of this society was held on May 15th and was devoted to the exhibition of patients and specimens; Dr. A. G. MILLER, the President, was in the chair.

Dr. ALEXANDER BRUCE showed two patients. The first was a girl who exhibited almost complete Paralysis of the Right Brachial Plexus. The accident which produced it was peculiar in that the girl was working at a carding mill throwing lint on to a travelling band. No one saw how the accident occurred, but the girl remained unconscious for 20 hours. There was no external injury but complete loss of power in, and almost complete anæsthesia of, the right arm were manifest on her restoration to consciousness. The condition had not improved in the least since the accident but a progressive atrophy of the muscles had ensued. The galvanic current gave only a very feeble muscular reaction while there was none with the faradaic current. The right hand showed great lividity and coldness (being 14° lower in temperature than was the right hand) and there was transverse grooving of the nails. Over the region supplied by the circumflex nerve there was good sensation, as was almost invariably found in paralysis from rupture of the brachial plexus. The right shoulder was higher than the left, due to over-action of the trapezius. The injury to the first dorsal nerve at its root was shown by its action on the sympathetic nerve fibres going to the eye: the right palpebral fissure was smaller than the left, the eyeball was less prominent, and the pupil was smaller. There was flattening of the right cheek, which occurred very frequently in such cases and which was difficult to explain. The serratus magnus and the rhomboid muscles had escaped paralysis. The second case was one of Disseminated Sclerosis occurring in a young woman, aged 22 years. The disease had lasted for two years and now she was almost unable to walk. The intention tremors were most marked, as was also nystagmus.

Dr. BYROM BRAMWELL exhibited two cases. The first was that of a sailor, aged 41 years, with a peculiar form of Muscular Atrophy. The affection began two and a half years ago after the patient had slept in the open air all night. Loss of power was first noted in the muscles belonging to the left big toe, from which it spread to the neighbouring muscles. Two or three months later the right foot became similarly affected. About nine months subsequently the right and then the left hand became paralysed. He was unable to feed himself and could hardly walk; he also suffered from some cramp-like pains in the legs. His health was otherwise perfect and there were no sensory disturbances or affection of the bladder or rectum. The condition remained stationary for about a year and then improvement commenced, so that he could now walk two or three miles, though with a duck-like gait. There was still marked muscular atrophy. The disease was not the ordinary form which began in the hands and only later extended to the feet. In this case it clearly began in the feet and even now affected only the muscles below the elbow and knee-joints. The gait was characteristic of paralysis of the muscles of the front of the leg. The diagnosis was difficult owing to the peculiar distribution and mode of origin of the disease. It was not ordinary peripheral neuritis and there had never been any muscular tenderness The question of its being beri-beri was discussed and excluded. A few German authors had described similar cases. It was evidently a distinct type of disease The knee-jerks were rather diminished. The second case was one of Syringomyelia. The man was admitted to the ward on account of Bright's disease. While there it was noted that the small muscles of the hands (especially on the left side) were markedly atrophied; the fingers had the claw-like appearance. The same condition was present in the right hand and it extended in both cases to the forearm. Tactile sensation was good but that to painful impressions was entirely lost in that part of the skin extending upwards from the umbilicus. The sensations to heat and cold were less markedly altered. There were painful sores on the hands and scars of burns on the back due to his sleeping on a hot boiler, the heat of which he was unaware of. His head was not symmetrically shaped. It was a case of syringomyelia and such cases were very often mistaken for progressive muscular atrophy.

Dr. E. CARMICHAEL showed a man suffering from a Hypertrophic Condition of the Integument, probably due to distended lymphatics. The swelling extended from the right buttock down to the foot. The affection began eight years ago and now the right knee was completely disorganised.

Mr. FRANCIS M. CAIRD exhibited two patients The first was a man, aged 51 years, who had undergone an operation for the Removal of the Pylorus. The patient had lost weight greatly and had an epigastric tumour. A test meal showed that he possessed an excess of hydrochloric acid and some lactic acid. The pylorus was closed, as was also the pyloric end of the stomach, while the jejunum was stitched up and made to open into the posterior part of the stomach. The man had improved greatly since the operation. The second patient was a man who had a very large Growth in his Epigastric Region and was greatly emaciated, weighing only 7 stones 10 pounds. A test meal showed the entire absence of hydrochloric acid. Posterior gastro-enterostomy was performed, but the tumour was left as the patient was excessively weak. The man has put on flesh rapidly and now he weighed 9 stones 6½ pounds, while the tumour had disappeared.

Mr ALEXIS THOMSON showed a woman on whom he had performed Enterectomy for Multiple Tuberculous Strictures of the Small Intestine. The patient suffered from a chronic incomplete stricture of the small intestine which might be either tuberculous in nature or even invagination of the bowel. Visible peristalsis was noted. The woman had suffered from inflammation of the bowels nine years previously. On opening the abdomen a number of enormously distended coils of intestine were seen, along with great matting and miliary tubercles on the serous surfaces There were about five tuberculous strictures, none of which would admit the tip of the little finger. Mr. Thomson had removed 22 inches of bowel in two stages, first making a fistula and clearing out the bowel and later resecting the intestine.

Dr. FRANCIS BOYD showed a young woman suffering from Stenosis of the Pulmonary Valves. She was admitted to the Deaconess Hospital suffering from rheumatic fever and exophthalmic goitre. The murmur was systolic in time with its point of maximum intensity in the second left interspace. There was no cyanosis as happened when the lesion began during fœtal life. The patient had a previous attack of rheumatic fever and probably the lesion dated from that time.

Mr. HAROLD STILES showed a boy after operation for Idiopathic Cerebral Hæmorrhage. The symptoms were those of ordinary apoplexy occurring while the boy was perfectly well. He had been rather unable to do his sums or to read well while at school In the afternoon he felt dizzy and had nine convulsions between 5 P M and 2 A M. when he developed left-sided hemiplegia. He was never entirely unconscious Next morning he had somewhat improved in mental condition though the paralysis was as marked. There was no history of traumatism It was at first thought to be an aberrant case of tuberculous meningitis, but as his symptoms did not improve Mr Stiles trephined over the right parietal bone as it was there that he had complained of pain On opening the dura mater the brain bulged far outwards and cracked in two places, giving exit to several blood-clots On introducing the finger several more clots were felt in the ventricles and these were scooped out Next morning the boy was much more conscious and he stated that the pain was gone There was a very great flow of cerebro spinal fluid for a few days, but in eight weeks the wound had entirely healed and now there was no trace of paralysis

Mr. J. M. COTTERILL showed two cases. The first was that of a woman with a deep Rodent Ulcer under treatment by the x rays The disease developed six years ago and three years ago the right eyeball had to be removed as well as part of the bone It remained healed for 18 months when it recurred. The treatment by the x rays had been continued for four weeks, during which time the ulcer had greatly improved, the pain being much less, the fœtor less marked, and the edges beginning to cicatrise The second case was a Joint Affection in a Hæmophilic Lad The left elbow presented many of the appearances of tuberculous disease, but there was no pain on pressure Several years ago the same patient presented himself with exactly a similar condition in the knee-joint. It was learned that he was a bleeder and so Mr. Cotterill did not think it advisable to operate He introduced a trocar into the knee joint and withdrew blood Ultimately the knee-joint recovered perfectly. The swellings in both knee and arm had persisted for long and both were probably due to long-continued bleeding into the joints

Dr A SCOT SKIRVING showed (1) A Brain showing the track of a Mauser bullet completely traversing the organ; (2) a Brain from a case simulating Rupture of the Meningeal Artery; (3) specimens illustrating the Effect of Bullet Impact; (4) a Stomach nine days after Operation for Perforation; and (5) a large Perineal Tumour (five pounds in weight) from a man, aged 80 years, who had carried it all his life

Dr BRUCE showed microscopical specimens and photographs of (1) Progressive Muscular Atrophy; (2) Amyotrophic Lateral Sclerosis; and (3) Glioma of the Pons

Mr. CAIRD showed · (1) A Tumour of the Pylorus; (2) Vesical Calculi; and (3) Vesical Papillomata

Mr THOMSON exhibited · (1) Two Feet of Small Intestine showing four tuberculous ulcers; and (2) a form of Syringe for Iodoform Injections, &c.

Dr. LOGAN TURNER showed: (1) Two Casts showing Congenital Malformation of the Auricle, and (2) a Larynx from a case of Primary Laryngeal Diphtheria

[illegible] ntestines from a case of so-called [illegible] Colon, and (2) Sarcoma of the [illegible] months.

EPIDEMIOLOGICAL SOCIETY.—A meeting of this society was held on May 17th, Dr. Patrick Manson, the President, being in the chair —Dr. E. Klein read a paper, which under the title of "What is Plague?" was a description, illustrated by lantern slides, of the bacteriological characteristics of typical Oriental plague He imagined that when the plague was raging as an epidemic there could be no difficulty in its diagnosis by men familiar with its clinical and pathological features, nor much when well marked cases occurred on board a vessel arriving from a plague-infected port, but there were circumstances under which a diagnosis could not be made without the aid of the bacteriologist, though happily the evidence thus afforded was unmistakeable. Dr. Klein then described two such cases in which the evidence was positive and one which led him to a negative conclusion The first was that of a sailor on board a vessel arriving in the port of London from Japan, Manila, and Hong-Kong, who had had for four weeks a huge swelling in the right groin that had suppurated and when incised discharged a quantity of foul grumous pus The next was that of a Lascar, who, taken ill on Feb 28th, was landed at a south-western port on March 12th, and, the vessel having obtained *pratique*, he was sent to the general hospital, the bubo being regarded as traumatic. In neither case had the patient been isolated, but none of the crew had been infected. The Lascar had a temperature of 103° F., and the disease had already assumed the septicæmic type Pus from each case was sent to Dr Klein, who found, among other bacteria, many which were typical of plague, the diagnosis being verified by subcutaneous and inoculation experiments. The third case was that of a boy who had never left London and was admitted into a hospital with inflamed glands. There was no evidence of the possibility of plague infection beyond the fact that his mother was a dealer in rags and old clothes, but cultures, subcultures, and inoculation experiments, with the bacteria, obtained first from the juice and later from the pus of the glands, alike gave negative results. The conflicting statements as to the infectivity of plague were easily explained by the difference between the types of the disease. In the pneumonic form the pulmonary exudation and expectoration teemed with the bacillus; in the septicæmic or hæmorrhagic types they swarmed in the blood, and hæmorrhages took place through the mucous membranes of the respiratory, alimentary, and urinary organs, but in the bubonic type they were rarely found in the blood and were practically limited to the spleen and lymphatic glands, so that until the bursting of the glands and the escape of the pus the possibilities of infection were small. In his experience the bacilli did not, as had been alleged, disappear when suppuration took place, and he felt that the failure to recognise the true nature of a non-venereal bubo might lead to disastrous results For instance, a seaman discharged in the Tyne on Oct 4th from a vessel arriving from Rosario travelled thence to Llandaff where he was taken ill and sent to the General Hospital on Oct 2nd, dying some days later from plague Had the abscess burst previously he might have been the centre of an outbreak of plague in the places where he happened to be at the time The bacillus pestis was morphologically fairly characteristic, blunt, straight, thick, with the protoplasm staining at the ends, leaving the middle third lighter. It did not liquefy gelatin but formed colonies with filmy margins and angular outlines In ghee broth the cultures formed a layer on the [illegible] talactite-like prolongations and [illegible] o the bottom of the flask like a [illegible] secreted a viscid material by which they adhered in clumps and to such an extent in agar that the culture could not be emulsified It was therefore impossible to verify agglutination in broths, but this adhesive material was dissolved by salt, and gelatin cultures could be then emulsified in the physiological solution, in which the blood serum of animals that had suffered from plague caused unequivocal agglutination in from 10 to 15 minutes when added in the proportion of 1 in 20, normal blood having no such action He had prepared a number of guinea-pigs by three successive injections of sterilised salt emulsions, and two of mild living cultures, and with their serums he had produced almost instant agglutination of the bacilli in cultures obtained from every part of the world. He had not yet had an opportunity of applying this test to suspected cases of plague in man, but in the preparation of Hoffmann's anti pest solution he had been able to test the samples, rejecting such as failed to confer agglutinative properties on the serum of animals inoculated with them.—Mr. J. Cantlie said that while there was no difficulty in recognising the marked types it was otherwise with the milder, and among the seven separate invasions during the past year he had been unable, except at Glasgow, to diagnose clinically any of the cases; three, indeed, had turned out to be leucocythæmia, glanders, and enteric fever. All cases of fever with enlarged glands, not venereal, should, however, be deemed suspicious, and he believed that some of these, one of which he described, might be cases of pestis minor, being indistinguishable from those that in the East, preceded, accompanied, and followed epidemics.—Dr. E J McWeeney of Dublin suggested that even if they did not fulfil Dr. Klein's bacteriological requirements they might develop into the true plague, that the virus *vires acqueret eundo* —Dr. Herbert Williams said that cases such as those mentioned by Dr Klein might easily escape recognition, the more so since 5 per cent of Lascars had enlarged inguinal glands, but whenever there was suppuration or fever they were detained in the hospital of the Port of London and the contents of the glands were sent to Dr. Klein, when nearly all proved to be plague. It must not be forgotten that a venereal history did not exclude plague.—Dr. P. T. Adams remarked that at Bombay the plague was most prevalent in the cold season and during the monsoon when the cold or the rain led to overcrowding indoors. He believed that the infection nearly always gained access by some lesion, external or internal, as of the bare feet, or, in the case of the pneumonic form, catarrhs of the air-passages. Haffkine found that the bacillus was enfeebled by exposure to light and air.—Dr. Reginald Farrar could confirm the feeble infectivity of the bubonic type, nearly all the cases he had seen among Europeans having been pneumonic. The only exceptions were the little daughter of an officer who had been bitten by a sick, probably plague-infected, squirrel and a friend of hers, both of whom died. Visitors to the hospital very rarely contracted it; it seemed to cling to the soil Formerly the population used to migrate *en masse*, but now they often remained in the infected houses.—Dr. Bulstrode asked Dr. Klein what evidence he deemed conclusive and whether bacteriologists like himself were ever in doubt as pathologists and clinical observers often were? He would like to know Dr. Williams's definition of an infected port, for he believed that epidemics mostly spread by unknown channels.—Dr. Turner had been sent to inspect some 30 cases in Queensland, mostly among Europeans; the majority were bubonic, one only was pneumonic, and but few were septicæmic. In none could he trace direct personal infection, except, perhaps, in the case of a post-mortem room porter. There not one of from 300 to 400 "contacts" contracted the disease, and very few of the thousands at Sydney. In Brisbane, Port McQuarie, and Cairns the rats were affected before the people were.—The President said that though Dr. Edington had stated that the rats were not affected at Cape Town, Dr. W. J. Simpson had found numbers of dead ones under the floor of infected houses and that it was an error to believe that the fleas of rats did not attack man. Doubtless, like those of dogs and fowls, they preferred their respective hosts, but like these they would bite man in default of their natural prey.—Dr. Klein, replying, stated that Dr. Edington now admitted the mortality among rats at Cape Town, and had sent cultures obtained from them to several bacteriologists, including himself. There was no doubt as to their being true plague bacilli, Dr. Edington's failure to recognise them having been due to his employing unsuitable media. As to the evidence he relied on that derived from cultures and subcultures confirmed or negatived by inoculation experiments, to which in future he would add the serum or agglutination test; when these agreed there could be no room for doubt.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—An ordinary meeting of this society was held on May 17th at the Victoria Hospital for Children, Chelsea, S.W., Mr. D'Arcy Power being in the chair.—Mr. W. J. Susman exhibited, for Dr. Walter Carr, a case of Anæmia Infantum Pseudo-leukæmica. The child was admitted in January, 1901, and the spleen then reached down to the pubes, while the blood showed the characteristic changes described by von Jaksch in 1890. At the present time the spleen could be felt two inches below the costal margin. Cod-liver oil, iron, and mercury had been administered.—Dr. Wayland C. Chaffey inquired whether the remarkable reduction in the splenic enlargement was attributed to medicine or to diet.—Dr. Edmund Cautley thought such cases were unconnected with rickets or syphilis. The prognosis was extremely favourable.—Mr. Susman, in reply, said that beyond a "hot-cross bun skull" the patient showed no sign of either syphilis or rickets. In the treatment of these cases Dr. Walter Carr placed considerable dependence on iron.—Mr. Susman showed, for Dr. Montague Murray, a case of Spastic Paraplegia with Cerebral Symptoms. The disease followed whooping-cough and fright at the age of four years. There was no history of congenital syphilis. The symptoms included loss of power in the legs and to a less extent in the arms, a spastic gait, increased reflexes, widely dilated pupils, and defective intelligence. They could not apparently be classified under any recognised disease.—Dr. Edmund Cautley regarded the case as one of cerebral sclerosis, probably set up by encephalitis due to some infective fever. It resembled, he thought, the group of cases originally described by Little.—Mr. Alfred H. Tubby suggested a cerebral diplegia as the cause of the symptoms. It was important to distinguish such cases from Little's disease. Prognosis was bad.—Dr. J. Blumfeld inquired why the pupils were dilated.—Mr. Susman, in reply, said that nothing abnormal could be detected in the fundus oculi and no explanation could be offered of the dilated pupils, which reacted to light and to accommodation.—Mr. D'Arcy Power showed a case of Sporadic Cretinism which had been under the care of Dr. Wallis Ord in 1893.[1] The patient was now 11 years of age, and thyroid extract had been given for eight years. The child showed practically no signs of cretinism and was in the third standard at school.—Dr. Robert Hutchison remarked that under thyroid treatment there was generally greater improvement in the bodily than in the mental condition. But the present case proved how much might be done to improve the intelligence if treatment was commenced early in life. — Mr. Power, in reply, said that four and a half grains of thyroid extract had been given per diem.—Mr. D'Arcy Power showed a lad, aged nine years, who had suffered from Paroxysmal Hæmaturia and Albuminuria with Attacks of Renal Colic. The symptoms improved when the patient was in hospital, but they recurred when he returned to school. Hoping to find a stone Mr. Power had explored the right kidney by the lumbar route, but no obstruction was found either in the kidney or in the ureter. The wound speedily united, and the lad was on the eve of leaving the hospital when he showed signs of scurvy. This yielded to the ordinary remedies and there had been no recurrence of renal symptoms.—Dr. G. A. Sutherland thought that the hæmaturia, but not the pain, might be explained by scurvy. Was there any hæmoglobinuria in the case?—Dr. George Carpenter said that hæmaturia was not uncommon in children and that it usually got well under hospital dietary.—Dr. Blumfeld remarked upon the fact that the child developed scurvy whilst in hospital.—Mr. Power, in reply, stated that there was no hæmoglobinuria. The child was only a week or so in hospital before he showed signs of scurvy, which was possibly determined by loss of blood. The patient also passed mucus and blood by the bowel.—Mr. D'Arcy Power showed a child with a large Artificial Anus in the scrotum, following an operation for irreducible hernia.—Dr. George Carpenter read an abstract of his Investigations upon the Urine of an Infant from the age of 27 days onward. The fluid was systematically collected and was found to average 19½ ounces in the 24 hours, the largest quantity passed at any one time being four ounces. The specific gravity was generally from 1001 to 1002, never above 1005; a trace of albumin was invariably present. The quantity of urea was notably small, usually from a quarter to one-sixth of a grain per fluid ounce; the total amount passed in 24 hours varied from two and four-fifths grains to four and a half grains, averaging three and a half grains. Casts were not found. Dr. Carpenter gave an abstract of earlier observations on the subject, his own figures being on the whole considerably lower than those previously recorded.—Dr. Sutherland inquired whether the infant was in good health and breast- or bottle-fed.—Dr. Cautley requested particulars as to methods adopted in estimating urea and in searching for hyaline and granular casts.—Dr. Hutchison inquired whether the bodily weight was noted, since that would influence the proportion of urea. He had generally found that the amount of urea passed by infants was under-estimated. It was important to guard against any fallacy on the question of bottle-feeding.—Dr. Carpenter, in reply, said that the weight was not systematically recorded. The infant was bottle-fed, and took 20 ounces of fluid in 24 hours. Urea was estimated by Southall's bromide method. Casts were sought with the microscope after the urine had been carefully centrifuged.—The next meeting of the society will take place at Liverpool on Saturday, June 29th.

CLINICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on May 21st, Dr. A. Wahltuch being in the chair.—Dr. A. T. Wilkinson demonstrated three cases of Lobar Phthisis and commented on the acute onset and chronic after-course of many such cases.—Dr. Milligan showed two cases of Tuberculous Disease of the Middle-ear and Adjoining Mastoid Cells In the first case, that of a child, aged one year, the disease had lasted ever since the child was five weeks old and had commenced with painless origin, the first symptoms noted being discharge from the ear, very shortly afterwards followed by facial paralysis. The peri-otic ganglia soon became enlarged and at the time that the child was admitted to hospital, five months after the commencement of the *trouble*, extensive disease within the middle-ear and mastoid process was found. Retro-auricular drainage was decided upon and at the present time satisfactory progress was being made, the treatment consisting mainly in antiseptic irrigation of the part. In the second case there was no facial paralysis; operative interference was undertaken with satisfactory results. A case of Lupus of the Right Nasal Chamber and of the Right Half of the Larynx was also shown. The patient, a *female*, aged 25 years, had suffered for three years and at the time of admission to hospital was complaining of considerable huskiness and slight stenosis of the right nostril. The right free margin of the epiglottis was infiltrated, numerous *lupoid nodules* being found upon its free margin, but no ulceration was detectable. Dr. Milligan made some *remarks* upon the course and treatment of tuberculous affections of the middle-ear and of the mucous membrane of the nose.—*Mr. G. H. Lan*[illegible] Skin Disease belongi[illegible] bacillary tuberculides [illegible]ly all the elements of [illegible] fore inoculable. (1) [illegible] which had commenced within the nares and spread externally by the nasal duct, showing remains of a dacro-cystitis; (2) A case of lupus verrucosus of the hand; (3) tuberculous ulceration, with epithelial proliferation, in the back of the hand, the result of a bite (glandular infection also along the arm); (4) extensive lupus vulgaris of the arm of 12 years duration apparently cured (six months ago) by pyrogallol dressings; and (5) scrofuloderma in the cheek of a child of typical tuberculous physique. There was no family *history* whatever of *tubercle*; the other children were healthy. 2 Toxin tuberculides in which the lesions presented giant-cells and epithelioid cells for examination, but no bacilli; not inoculable. One example only was shown—"papulo-necrotic toxi-tuberculide" as described by Hallopeau. Lesions were seen in groups, chiefly on the elbows and the knees. Small brownish-red papules with umbilicated necrotic centres were seen in various stages, among the earliest being a papule of the size of a pin-head and generally occupying the site of a hair follicle. Importance was attached to this group as indicating the presence of a tuberculous focus elsewhere in the body.

---

[1] THE LANCET, Nov. 4th, 1893, p. 1114, Case 2.

GLASGOW SOUTHERN MEDICAL SOCIETY.—A meeting of this society was held on May 9th, Dr William Watson, the President, being in the chair. The committee appointed by the society to draw up a representation to the General Medical Council in regard to their decision respecting the sale of drugs and poisons presented for consideration the following petition which was read and approved.—

Unto the Hono[illegible]

[illegible] the sale of drugs and poisons persons who are not qualified to act as chemists or pharmaceutical assistants, and thereby causes such persons *to commit* breaches of the Pharmacy Acts," it was unanimously resolved to lay before your honourable Council some of the points brought out in the discussion and to humbly pray that in *your further* deliberations on the case of Dr. Thomson you will take them into your favourable consideration. Firstly, your petitioners would remind you that the practice of keeping open shop, surgery, or dispensary in which drugs may be sold has been the custom in Glasgow and the west of Scotland from time immemorial This right is retained to this day and is distinctly conserved in the Pharmacy Amendment Act of 1869, which expressly states that medical practitioners shall not be affected by the first 15 clauses of the Pharmacy Acts. Your petitioners [illegible] submit, therefore, that medical [illegible] to practise pharmacy in the [illegible] Pharmaceutical Society; and, f[illegible] in this part of the kingdom of keepi[illegible] ance with the laws is most conven[illegible] been long educated to its use; and is practically necessary in many localities for the medical practitioner in the discharge of his professional duties Secondly, with reference to the [illegible] point out that the employ[illegible] assistants for the sale of [illegible] scheduled in the Pharma[illegible] the law Moreover, the [illegible]ing or poison except scheduled poison is the undoubted right of every citizen. Your petitioners fail, therefore, to see any reasonable cause for the *condemnation of the practice* of selling drugs and poisons—always excepting scheduled poisons—by trained drug assistants even though unregistered; *especially* in view of the fact that the sale of them is a common and legal act by persons who make no pretence to special [illegible] regarding general medical practice in Glasgow and the west *of Scotland*. On behalf of the Glasgow Southern Medical Society, containing over 200 members, your petitioners would express the earnest hope that the prayer of this petition will receive at the hands of your honourable Council due consideration and approval. And your petitioners will ever pray.

Signed in name and on behalf of the Glasgow Southern Medical Society in meeting assembled and the seal of the society affixed thereto at Glasgow this ninth day of May, one thousand nine hundred [illegible]mary.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—The annual meeting of this society was held at 20, Hanover square, W., on May 22nd, Dr. A. J. Harrison, *the President, being in the chair.*—Dr. C. H. Thompson showed a case of Adenoma Sebaceum in a woman, aged 27 years. The affection dated from infancy and the patient's mental development was poor.—Dr. W. T. Freeman showed a case of Lupus Erythematosus in a young man who had previously come before the society and had greatly improved under escharotic treatment.—Dr. T. D. Savill brought forward a case of Molluscum Fibrosum in a young man, shown to the society six months ago. In the interval the treatment adopted had been painting the tumours with sodium ethylate and some improvement had resulted.—Dr. Graham Little showed a case of Purpura of extensive distribution in a boy, aged 12 years —Dr. H. Waldo exhibited drawings of a case of Lupus Erythematosus, with multiple and symmetrical lesions. The patient had been under observation for some years after the drawings were made and was brought up by Dr. Waldo to this meeting to illustrate the almost complete disappearance of the lesions as figured in the drawings.—The President exhibited some microscopical specimens of Anthrax Bacilli and spores, kindly furnished from an unpublished case by Dr. J. O. Symes of Clifton, Bristol.—Mr. George Pernet showed a microscopical preparation of Fungus from a case of Tinea Unguium.—Dr. Waldo then read the Annual Address, choosing as his subject Lupus Erythematosus, and invited discussion of his paper under the following heads. 1. The clinical and pathological features of lupus erythematosus. 2. What was its etiology? 3. Was it related to lupus vulgaris? 4. Experiences of acute severe generalised forms described by Kaposi. 5. Mental *phenomena associated* with it. 6. *Could it be always distinguished* clinically?—Dr. Harrison, Dr. J. H. Stowers, Dr. Phillips-Conn, and Mr. Pernet took part in the discussion which followed the paper.—The election of officers *for the ensuing session was then proceeded* with and resulted as follows:—President: Dr. Harrison. President-elect: Dr. Stowers. Vice-Presidents: Dr. H. A. G. Brooke, Mr. Alfred Cooper, Dr. H. Radcliffe Crocker, Sir George Duffey, *Dr. Robert Liveing, and Dr. P. S.* Abraham. Treasurer: Dr. William T. Freeman. Honorary secretaries: Dr. Little and Mr. Arthur Shillitoe. Council: Mr. Hope Grant, Mr. Thomas J. Hitchins, Mr. George Pernet, Dr. *Phillips-Conn, Dr. H. Leslie Roberts, Mr. George* Sequeira, Dr. R. Travers-Smith, Dr Edward Stainer, Dr. F. Rufenacht Walters, Dr. Wilfred B. Warde, and Mr. Campbell Williams.

A CENTENARIAN.—It is stated that Mrs. Neve of St. Peter Port, Guernsey, who was born in the year in which Louis XVI. of France was guillotined and Napoleon Bonaparte left Corsica, completed her one hundred and eighth year on May 18th. She was born in the house in which she now lives.

Reviews and Notices of Books.

Surgical Experiences in South Africa, 1899-1900. By GEORGE HENRY MAKINS, F.R.C.S. Eng., Surgeon to St. Thomas's Hospital. London: Smith, Elder, and Co. 1901. Pp. 486. Price 16*s*.

THIS book, which is mainly a clinical study of the nature and effects of injuries produced by bullets of small calibre, is a record of Mr. Makins's personal experiences, and as such is a valuable contribution towards that more complete surgical history of the South African war which will no doubt be undertaken by a responsible military medical officer when the whole of the statistics are available. The general trend of the observations goes to show that the employment of bullets of small calibre is all to the advantage of the men wounded, except in so far as the increased possibilities of the range of fire may augment the number of individuals hit; also that such variations as exist between wounds inflicted by bullets of the Martini-Henry and Mauser types respectively depend rather on the form and bulk of the projectile than on any inherent difference in the nature of the injuries. The main peculiarity of the deeper injuries is the frequent strict localisation of the direct damage to an area of no greater width than that crossed by narrow structures of importance such as arteries and nerves. Mr. Makins tells us that of surgical diseases the one most special to the campaign was the veldt sore. His experience is opposed to the hurried removal of the wounded from the field of battle and he feels strongly in favour of stretcher parties for this work. His observations also strongly illustrate the necessity of possessing stationary hospitals of greater mobility and a higher degree of equipment than the service at present possesses. He thinks that the amalgamation of the field hospital and bearer company into one unit is much to be desired, both for economy of working and the more equal distribution of duties to the medical officers engaged. Mr. Makins is an advocate for the substitution of the tortoise tent for the service marquee, for while admitting a warm preference for the appearance of the service pattern he says: "I think it is indubitable that the other is the more useful." In his remarks on the difficulties of operative surgery he alludes to the lack of facilities experienced in getting water for use at operations and to the draughts in the tents carrying the dust from the camp, the latter as one of the commonest troubles. While praising the excellence of the field hospitals Mr. Makins indicates that the stationary hospitals were not, in his opinion, so perfectly conceived or organised, and he remarks that the difficulties experienced in supplying all that was necessary will, he hopes, go far towards securing greater facilities and rights of transport to the Royal Army Medical Corps in the future.

Mr. Makins lays stress on the circumstance that the experience of the present campaign has scarcely justified the early prognostications expressed as to a greater increase in the number and severity of wounds amongst the combatants, the comparative immunity being explained on two grounds—the increased distance which for the most part separated the two bodies of men, and the want of effectiveness of the small-calibre bullet as an instrument of serious mischief. His observations lead him to the conclusion that at mean ranges, both in striking force and as regards the area of the tissue affected, the Lee-Metford is a superior projectile to the Mauser. On the other hand, the ease with which the latter undergoes deformation renders it the less desirable bullet to receive a wound from when not in its normal shape and condition. With reference to entrance and exit wounds he observes that when the range has been short and the velocity high it is often difficult to discriminate between the two apertures, but there is a general tendency of the margins, and even of the area surrounding the exit wound itself, to be somewhat prominent. The wound of exit offers far more variations in appearance than does that of entry. He draws attention to the multiple character of the wounds, to the small "bore" of the tracks, and to the tendency of the injury to be localised to individual structures of importance. The most striking examples of small even tracks were seen in punctures of the elastic and practically homogeneous lung tissue where the wounds were extremely small. He tells us that the tendency of simple wounds to run an aseptic course was very marked, and when suppuration did occur, with apertures of the normal small type, this was always the result of infection from the skin. While not claiming any cauterising action on the tissues by the bullet Mr. Makins inclines to the probability of the heat to which the surface of the bullet is exposed exerting a cleansing action on the projectile, and he remarks that the frequency with which portions of cloth were introduced from the kilt was one of the strongest surgical objections to its retention as a part of active service uniform. He is inclined to think that a general tendency to primary union and the absence of suppuration will always be a feature of wounds from bullets of small calibre, a mechanical factor of great importance existing in the spontaneous collapse and automatic apposition of the walls of the track. The illustrations of ruptured ricochet and grooved bullets are very instructive; it is extraordinary into how many fragments a Lee-Metford or a Mauser bullet may break up if it strikes a hard body while travelling at a high rate of velocity. Fragmentation is shown in some of the skiagrams. On the whole shock was by no means a prominent symptom in the small-bore injuries of soft parts; although initial pain might be slight or absent, all the patients complained of pain of varying severity at the end of an hour after the reception of the wound. In nearly all cases the rush of the bullet determined the initial flow of the blood from the exit wound, and this aperture usually furnished any hæmorrhage of importance. Mr. Makins corroborates Colonel W. F. Stevenson's observations[1] that limbs, the subject of marked local shock, are specially liable to furnish septic discharges. In speaking of primary hæmorrhage Mr. Makins says that external hæmorrhage from the great vessels of the limbs, or even of the neck, proved responsible for a remarkably small proportion of the deaths on the battlefield, but that a considerable number resulted from primary internal hæmorrhage. Secondary hæmorrhage in simple wounds of the soft parts by small calibre bullets was, he says, decidedly rare. The experience of the campaign fully bears out that of the past as to the steady increase of the number of aneurysms from gunshot wounds in direct ratio to diminution in the size of the projectiles employed. Uncomplicated cases of aneurysmal varix, as might be expected, were less common than were those in which the arterio-venous communication was accompanied by the formation of a traumatic sac. Mr. Makins expresses a strong opinion to the effect that in these injuries no operations should be undertaken before a period of from two to three months after the injury unless there is evidence of progressive enlargement. In the chapter on Injuries to the Bones the following are given as the special features of fractures caused by small-calibre bullets: (1) the nature of the exit wound which in a proportion of cases exhibited the so-called "explosive" character; (2) the presence of "local shock"; (3) the striking contrast of clean perforation and extreme comminution in different cases; (4) the occasional occurrence of fractures of a very high degree of longitudinal obliquity,

---

[1] Wounds in War, p. 83

(5) the rarity of transverse fracture; and (6) the tendency of longitudinal fissuring to stop short of the articular extremities of the bones. Perforations, although common in cancellous bone, were rare in the compact shafts, but Mr. Makins saw several such complete pure perforations. He draws attention to the great effusion into the knee-joint resulting from the vibration transmitted to the limb in the case of fracture of the femoral shaft. All short range lesions of the short bones seen by him were of the perforating variety. Of all the splints he saw in use he thinks the best were wire splints and the Dutch cane folding splints which are duly depicted in this volume. Of fractures of the pelvis he writes: "When uncomplicated they were of little more importance than simple wounds of the soft parts" He never saw a stellate fracture of the ilium. Fractures of the femur formed one of the most serious classes and one of the most fertile sources of mortality in the base hospitals. Mr. Makins has no doubt that Hodgen's splint is the best method of treating fractured thigh in the stationary hospitals The introduction of small-calibre bullets has robbed joint injuries of much of their importance; during this campaign clean wounds of joints were little more dreaded than wounds of the soft parts alone. The chapter on Injuries to the Head and Neck reveals many points of great interest, and the author feels certain that a long roll of secondary troubles await record in the near future. Injuries implicating the spinal medulla appear to have been proportionately the most fatal of any in the whole body to the wounded who left the field or field hospital alive.

Mr. Makins writes in regard to prognosis that wounds of the chest furnished the most hopeful class of the whole series of trunk or visceral injuries, and he relates the striking fact that the most common and troublesome complication of wounds of the chest, hæmothorax, was usually the result of wound of the chest-wall and not of the lung. Secondary empyemata not uncommonly followed incision of the chest or excision of a rib for draining a hæmothorax.

The pages devoted to the treatment of pulmonary wounds are very practical and are carefully written, and the cases and charts are very instructive. No chapter of military surgery was looked forward to with more eager interest than that dealing with wounds of the abdomen and in none did greater disappointment lie in store. Wounds of the intestinal tract, although they showed themselves capable of spontaneous recovery in a certain proportion of the cases observed, afforded but slight opportunity for surgical skill and the results generally deviated but slightly from those of past experience. Failure was due to the severity of the local injury or to the operations being necessarily undertaken at too late a date. In Mr. Makins's experience the wounds of the abdomen which proved the most dangerous were (1) wounds passing from one flank to the other; (2) antero posterior wounds in the area of the small intestines; and (3) wounds passing directly backward from the iliac regions. The 70 pages on injuries of the abdomen are well worth reading, but they lead the reader to the conclusion that surgical interference has been a failure and that the preconceived opinion, that laparotomy was in all cases of penetration the proper line of treatment, was certainly erroneous. In concluding his remarks on abdominal injuries, however, Mr. Makins adds that "the impressions are those that were gained as the result of the conditions by which we were bound in South Africa. ...... Under really satisfactory conditions nothing I saw in my South African experience would lead me to recommend any deviation from the ordinary rules of modern surgery."

The volume is well illustrated and Messrs. Smith, Elder, and Co. may be congratulated on the way in which they have published the work.

Congrès International de Médecine Professionnelle et de Déontologie Médicale. Edited by Dr. JULES GLOVER, General Secretary of the Congress. Paris: Masson et Cie. Pp. 697. Price 5 francs (free to Members of the Congress).

THIS is the official report of the International Congress of Medical Deontology and Ethics which was held, under the patronage of the French Government, at the Paris Faculty of Medicine in July, 1900. At the time we published lengthy articles from our Special Correspondent describing this congress, but, of course, it was impossible within the limits of our space to deal fully with all the papers read and the discussions that followed. Even the 697 pages before us do not give the discussions in full, for the congress was divided into several sections and sat during a whole week. Though this was the first time that a congress dealing exclusively with economical and ethical problems as they affect the medical profession had been held no less than 27 nationalities participated and were represented by 444 delegates and members. The Governments of France, Belgium, Portugal, Russia, Ecuador, Japan, Roumania, Austria-Hungary, the United States of America, Italy, Turkey, Norway, Sweden, and Venezuela sent official representatives to attend this congress and to report to their respective Governments upon the nature of the proceedings This showed on the part of these Governments an enlightened appreciation of the programme and probable influence of the congress. The questions at issue involved the legal, and what is, or should be, the illegal, practice of medicine, and in many other respects dealt with matters that must be partially, and sometimes wholly, settled by legislation. Though a Government only governs the people it represents, if several nations agree upon the necessity of certain reforms or new laws such a concurrence of opinion at least gives greater moral weight to the arguments of those who, in their respective countries, take the initiative in promoting legislation in this direction. Therefore, it is to be regretted that the British Government was not officially represented. It is further and still more regrettable that though Mr. Adolphe Smith, after reading a paper on the Organisation of the Medical Profession in Great Britain, was able to present a list of 35 British medical unions or associations formed for the special purpose of dealing with the questions which the congress had assembled to discuss, the number of British representatives actually present was very small. Fortunately, the publication of this list in the report before us will serve to show that the members of the profession in Great Britain and Ireland have taken action in many directions and that, if they were but feebly represented in Paris, they have not been idle at home.

The proceedings of the congress will serve to demonstrate very forcibly the remarkable similarity of the economical problems which face the members of the medical profession in all countries It will further show that in all countries the same idea prevails as to the means that should be employed to deal with the grievances that arise therefrom. On all sides the demand has arisen for organisation. The methods of organisation differ somewhat in the various countries, but the object is always the same. In Belgium, France, and the United Kingdom the mode of action—the formation of independent medical unions—is similar. In Germany and Austria the tendency is in favour of medical chambers, which differ from unions, associations, syndicates or guilds in so far as they are official organisations possessing legal powers, and with membership rendered obligatory by law. But in action both strive for the same end—the maintenance of the dignity of the profession and a high code of ethics, the prevention of abuse such as that involved by well-to do people availing themselves of medical charities or the degradation of the practice of medicine by the smallness of the remuneration paid for contract work. Then the conditions under which the practice of medicine should be allowed were also lengthily discussed and form part of the programme of all medical unions and medical chambers. As a branch of this latter subject we find the question of the medical man who practises in a foreign country, and on this Dr. J. Schwalbe, editor of the *Deutsche Medicinische Wochenschrift*, read a lengthy paper, reviewing the law of various countries with regard to foreign practitioners. Dr. Schwalbe concluded his paper by urging that protectionism should not interfere with scientific progress, but that, nevertheless, it arises as a natural consequence of the great and vital competition between nations which is becoming more and more keen every day. It is thus, he said, that hunger dominates generosity, just as might rules right. Therefore there is an ever-present reaction. On one side we see the great modern progress of science which serves humanity and intellectually unites the peoples of the world; while, at the same time, we see on the other side the increasing difficulties of material existence which have created the protectionism that economically divides nations one against the other. On this subject Dr. Greenwood, delegate of the Brussels Medical Graduates' Association of England, contributed a paper in which he maintained that academic distinctions and honours should be cosmopolitan, and that the State laws went beyond their province when they insinuated that degrees given by a foreign university were worthless. The proper criterion of a university's degree was, he urged, the opinion of the world.

On the question of hospital abuse a great amount of information was given, not only with regard to the hospitals of Paris and the principal French provincial centres, but also from many other countries. Thus the system of paying hospital patients which prevails, notably in Sweden, was explained and condemned. It was urged that hospital patients should be strictly examined as to the place where they live, the work which they do, the wages that they earn, and even as to the financial position of their near relations, so that the hospitals might be reserved exclusively for the treatment of the poor. But here a difficulty arose from the international character of the congress, as the question assumes a somewhat different aspect when the hospitals, as in England, are maintained by voluntary subscriptions and when, as in most continental countries, they are municipal institutions maintained by public taxation. Mr. E. Montefiore, on behalf of the Charity Organisation Society, contributed a paper on Hospital Abuse in London and advocated the formation of a Central Hospital Board for London. Of course, this centralisation does already exist where the hospitals belong to the municipalities. The question of poor relief taking the form of medical attendance on the poor in their own homes was also lengthily debated. Then there were the cases of accidents and the right of a person to be treated at a hospital when his employer had insured him against such accidents. This led up to the insurance companies, to the medical aid associations, to the friendly societies—in fact, to all the topics which in these columns we have grouped together under the general heading of the Battle of the Clubs. It is impossible here to summarise all that was said on these questions for it is spread over several hundred pages. The reader should consult the volume itself.

The injury that sometimes results from massage that is not performed under medical surveillance was explained and denounced, as also were all forms of special treatment practised by others than fully-qualified medical men. Then prescribing by druggists, the advertising of quack remedies and secret specialities in general newspapers, and many other manœuvres which deprive the medical profession of some of their clients and at the same time endanger public health, were lengthily discussed and energetically condemned. But the most delicate subject was that which comes more precisely under the denomination of "deontology"—namely, the relations of medical men towards each other. This discussion had for its basis a very lengthy and able paper by Dr. Grasset of Montpellier. But it was generally agreed that the duty of the medical practitioner towards his brethren in the profession has nowhere been clearly defined. Where, for instance, does advertisement begin and end? what about medical men who are shareholders in a hydro medical establishment, a sanatorium, or a drug manufactory? under what conditions can a patient when still ill change his medical adviser? what constitutes the consulting physician? what is the position of the travelling doctor? under what conditions may medical advice be given gratuitously? Fo all this a code of medical deontology is necessary, but wh possesses sufficient authority to draw up such a code? T create such an authority, to confer upon it the necessar moral weight, was the principal purport of the congress Dr. Grasset concluded by saying: "All we ask of th congress is this: that it will seriously consider one thing the creation of a superior council of professional medicin charged with fixing and interpreting the general principle of medical deontology (the duties of doctors to each other to be renewed by election only, on a very wide basis thus rising above questions of personal interests; having authority over all, by its origin, and from the independenc of its members; capable of creation without laws, and without imposing any financial tax; creating no new difficulty o hindrance to the free exercise of our profession; having only a moral authority, which is sufficient for honourabl persons who only ask to know what is their duty in orde to perform it."

These proposals being widely approved the congress agreed to meet again in 1903 at Brussels and, in the meanwhile, to endeavour to constitute an international committee, not only for the purpose of preparing for the next congress, but also to draw up a draft of a code on medical deontology. From these few words some idea may be gathered of the scope of the report before us. As it is the description of an international congress held in Paris, the greater part of the papers are published in French, but some are in English and German, and there are summaries of the more important conclusions in Italian as well as in English and in German. Altogether this is a valuable volume for all who are interested in the economical position of medical men and who are striving to organise the profession for the defence of its material interests and the maintenance of its dignity and high ethical standard.

Students' Manual of Medical Jurisprudence and Public Health. By G. HAXTON GIFFEN, L.R.C.P. & S Edin., Senior Demonstrator in Anatomy, Minto House, Chambers-street. Edinburgh: William Bryce. 1901. Pp. 330.

WE are not advocates for condensed text-books, but we believe that the author of this short work is correct in saying that in the first two portions, which are concerned with Forensic Medicine and Toxicology, there is a sufficient amount of information for the pass examinations of the Colleges, although we should hesitate to assent to the suggestion that a candidate could pass an honours examination simply from reading the pages of this volume.

The portion dealing with Forensic Medicine is well arranged and certainly contains a large amount of information in a small space. The use of comparative tables is largely taken advantage of, and these should be especially useful to the student to study immediately before presenting himself for examination, as it enables him to classify his knowledge in such a way that he can enlarge upon the facts so arranged more easily than by hastily reading over whole chapters. Illustrative cases are naturally not quoted in a book of this size. The accounts of the various poisons are brief but exact, the symptoms, post-mortem appearances, and tests receiving due attention.

In the third portion, that on Public Health, details of practical sanitation and methods of performing tests have not been included, as the book is not intended for either outdoor or laboratory work.

Our Army in South Africa. By R. SCOT SKIRVING, late Consulting Surgeon to the Australian Contingents. Sydney and Melbourne: Angus and Robertson. London: The Australian Book Company. 1901.

THIS little book, or pamphlet, of 43 pages is interesting and worth reading because of its freshness and of its stating the impressions of a civilian colonist who has actively pursued his medical calling in the field. It is mainly made up of the amplified entries of the daily journal which its author kept during the months which he spent at the seat of war in South Africa.

The author's observations extend over only a comparatively short space of time and a somewhat limited field, but they are, if of the "impressionist" type, nevertheless valuable because based on actual knowledge and experience. So far as regards his criticisms on the military aspects of the campaign he speaks with diffidence, knowing full well how a layman is likely to err when he criticises work altogether outside that of his own profession. But with respect to the medical aspects of the campaign he tells us in his preface that he feels on more familiar ground. He trusts that in anything he has said he may not hurt the sensibilities of that most gallant body of men—the Royal Army Medical Corps—and expresses a sincere desire rather to help the officers of that corps to a better position than to find fault and to suggest no remedy.

The subject has an interest at the present time and it is well to see how things struck an able civil surgeon without previous experience in war or any previous special knowledge of military organisation The author shrewdly remarks that the success which followed Lord Roberts's plan of campaign was partly due to the ignorance of strategy of the larger schemes of a campaign on the part of the Boer leaders, notwithstanding that they are past masters of all that pertains to individual warfare in a difficult country, "which aims at doing the maximum of evil to your enemy with the minimum to yourself." As we took an opportunity of saying at the beginning of the Boer campaign, they lost their great opportunity in not making at an early stage of the war a dash towards the coast. The author has not formed an elevated estimate of the Boer character, and he evidently thinks that had we throughout adopted severe measures hostilities would have been more quickly brought to an end Speaking of our non commissioned officers as a body he regards them as the very backbone of the British Army and looks to their much more frequent promotion to the commissioned ranks as a principal means of making the British army an efficient modern fighting force. In this war the special services—the artillery, the engineers, the transport, and the commissariat branches—appeared to him, as a layman, to be particularly well served. He thinks a British officer needs no artificial incentives to the display of personal valour and has evidently some misgivings lest the Victoria Cross should prove an incentive to rashness and a bait, even if of a very noble kind, for self seeking.

Touching the medical arrangements of the campaign the author has much to say. He thinks that if any grave blame attaches to anyone it should fall upon those who planned the campaign as a whole rather than on the medical heads and he advises the public to pause before they pass a hasty judgment based on Mr. Burdett-Coutts's representations He saw most of the horrors which Mr. Burdett-Coutts takes as his text and contends that the majority were wholly unavoidable, and as he was at Bloemfontein and was personally acquainted with all the circumstances he is in a position to speak authoritatively about all that he saw and describes What he has to say about the hospitals at this place and at Sterkstrom is worth reading. Taken as a whole it is strongly corroborative of all that we have maintained. "The fact," he says, "that the Australian medical units possessed their own transport gave them an enormous advantage in this respect over their imperial *confrères.* I am fully convinced that the ambulance service of an army ought to be quite independent of the transport department."

As regards the Royal Army Medical Corps, he believes "that no more honourable, hard-working, and willing set of public servants are to be found in Her Majesty's service. Many of the cruel things I have heard said of these men, who give freely of their best to the State, fill me with indignation. None the less, any outside observer can see plenty of faults both in the professional training of the men and the routine of the department." And to a consideration of these—more especially as to the point of professional training—he briefly addresses himself. Although we do not think that anyone, however able, who is not possessed of some military knowledge and experience is in a position to form any accurate opinion concerning many matters of army hospital organisation, we are nevertheless always glad to hail fresh and original views derived from recent and actual experience The author does not, by the way, approve of the practice of granting military titles to medical men, but medical officers would probably contend that if only he were in the army he would recognise the advantage that these confer, especially on field service, and that they simply follow and are a corollary of the unification scheme of army medical service organisation.

This little addition to the literature of the war by the late consulting surgeon to the Australian contingents may be taken, as we have said, as well worthy of being read and considered.

LIBRARY TABLE.

The Laws of Scientific Hand Reading By WILLIAM G. BENHAM. London and New York: G. P. Putnam's Sons. 1901 Pp. 650. Price 18*s* —This work, which is beautifully illustrated and got up, is evidently written by one who believes in his subject. Palmistry, like so many other quasi-scientific studies, has doubtless a substratum of truth. Thus the carriage of a person's hands upon his entering a room no doubt gives a partial clue to his character. The shape of the hands again gives indications of a particular diathesis and the effect produced upon the shape of the fingers—e g., clubbing—by various morbid conditions is known to every medical man. But that mounts and lines known under fanciful names give indications of qualities or of future events, or of things likely to lead to these events, is, we will not say impossible, but at any rate not proven. Mr. Benham's views upon physiology are peculiar. Thus on page 106 we find: "As an aid to memory .. . remember the vital life current entering the body through the tips of the fingers. The more pointed the tip the easier this current enters, *consequently the more direct the connecting link between the subject and its Creator.*" So on page 13 Mr Benham says: "At the moment the child is born and before it has given the first cry, or taken air into the lungs, the fingers extend with a *quick, spasmodic jerk.* . . I believe that *at the moment* the fingers of the child extend and become straight and rigid that *life*, the *vital spark* which sets the human machinery in motion, ... is projected into the child through the ends of the *rigid fingers* and thus becomes the gift of God to His creature."

Ballast By MYRA SWAN. London: Longmans, Green, and Co. 1901. Pp 360. Price 6*s* —We do not like the pathological novel. As yet in this country the novelist, although he or she discusses syphilis and drink, has not arrived at the treatment in romance of excessive morphiomania, or Sapphism, or vaginismus, all of which diseases will be found in French novels. But, on the whole, pathology is best treated in medical books. "Ballast" is apparently named after the principle with which Bottom's dream was named, for the heroine had no ballast, and hence she took to drinking, beginning with Vin Mariani and proceeding through absinthe to brandy. Her sister Grey, who nursed her with unparalleled devotion, is a very noble character and well drawn. Even she was erratic at times, as when with her lover in a hansom she remarked, "Smoke into my hair, so that when I brush it out the smell will remind me that it is not all a dream." It is rather reminiscent of the gentleman who said, "Pour it over me; I like the smell." But despite this one lapse from dignity we are sincerely glad that Grey eventually found happiness. We must give Miss Swan credit for her portrait of the dipsomaniac.

Modern Natural Theology. By F. J. GANT, F.R.C.S. Eng. London: Elliot Stock. 1901. Pp. 162. Price 2*s.* 6*d.*—Mr. Gant's little book consists of two parts—the first dealing with the testimony of a Supreme First Cause to be found in the workings of nature and the second with Christian evidences or apologetics. His argument is, shortly, that Christian evidences lead to the discovery of a Person who is "One with God and man," that this Person is One also with the Supreme Moral Lawgiver, and therefore One with a Personal Creator who is immanent in nature.

Jerusalem: a Practical Guide to Jerusalem and its Environs. By E. A. REYNOLDS BALL, M.A. London: Adam and Charles Black. 1901. Pp. 238. Price 2*s.* 6*d.*—Jerusalem is, in our opinion, a place which the traveller who does not wish to be disillusioned should avoid. Centuries of pilgrimage have—there is no other word—vulgarised it, and its associations, intensely sacred as they are and ever must be, will be better felt by imagination than if the quarrels between different bodies of Christians, to say nothing of the somewhat numerous fictitious holy places, are seen. But for those who wish to go to Jerusalem for the pleasure of "doing" it we can recommend Mr. Reynolds Ball's little book. It is clearly and simply written and there are some useful maps. We are glad to see by a quotation prefixed to the book that Mr. Reynolds Ball is acquainted with the delightful Evagatorium Fratris Felicis Fabri. Probably, except for the advent of modern tourist agencies and a railway, Jerusalem is much the same now as it was in the fifteenth century.

Atlas und Grundriss der Pathologischen Anatomie. (*Atlas and Elements of Pathological Anatomy.*) Von Obermedizinalrat Professor Dr. O. BOLLINGER. Band II., Zweite, stark vermehrte Auflage. 1901. München: Verlag von J. F. Lehmann. 1901. Pp. 190. Price 12 marks.—This volume of Lehmann's series appears as a second edition. It has been much enlarged and it now contains 72 coloured and 29 black-and-white illustrations, so that it forms a fairly complete atlas of that part of pathological anatomy with which it deals. The text consists of a somewhat brief account of the subject with descriptions of the plates. From these illustrations a student should be able to gather a very fair idea of the gross anatomy of many pathological conditions. It is, perhaps, advisable to mention that the work does not deal in any way with the minute anatomy of the diseases portrayed; that is contained in a special volume of pathological histology. As the coloured plates form the chief part of the work it is only right to mention that they are nearly all most admirably executed. In some cases, as often happens in coloured illustrations, the reds are too red and other colours are too pronounced, but these slight faults do not materially impair the accuracy of the drawings. The general get-up of the work is in accordance with what we have learned to expect from the publishers.

Eye, Ear, Nose, and Throat. By WILLIAM LINCOLN BALLENGER, M.D., and A. G. WIPPERN, M.D. With 165 Engravings and 6 Coloured Plates. London: Henry Kimpton. 1901. Pp. 512. Price 10*s.* net.—The portions of this book which deal with diseases of the ear, nose, and throat are less profusely illustrated than that which is devoted to diseases of the eye. In general the information given is good and there are many practical suggestions which are of distinct value; unfortunately, Dr. Ballenger commits himself to statements and advice which seriously detract from a work otherwise eminently suited for the class of readers for whom it is written, as examples of which we take the following. In the section on diseases of the ear Dr. Ballenger describes most minutely how and when to divide the various layers of the tympanic membrane; in that on the nose "swell bodies" is the term used for erectile bodies; and in that on the larynx Dr. Ballenger seriously states that a patient can adjust his epiglottis so as to enable the examination of the larynx to be easily made. It is the insertion of such careless or erroneous matter that renders the book unsafe; had the author confined himself to accepted views he would have been more successful in his task.

Cours de Minéralogie Biologique. Troisième série. Par J. GAUBE (du Gers). (*Lectures on Biological Mineralogy.* Third series. By J. GAUBE of Gers.) Paris: A. Moline. 1901. Pp. 331. Price 4 francs.—This volume contains a curious discussion upon the mineral composition of the muscles of man, woman, and of some animals. The author maintains that the degree of mineralisation has much to do with conditions of health and he suggests treatment by means of mineral matters that are normal to the human body in accordance with the indications from this point of view. Thus he speaks of the "remineralisation" of man and in the last lectures he discusses the biochemical properties of bacteria and the application of iodobenzyl iodide of magnesium in the treatment of bacterial diseases in general and in the treatment of bronchitic pneumonia in particular. The high rate of iron contained in the human muscle distinguishes it sharply from the muscle of animals. Again, woman's muscles differ from those of man by containing a greater quantity of organic matter, of potassium, and of soda and a smaller quantity of calcium and magnesium. We are not quite clear as to whether he means that the iodobenzyl iodide of magnesium has anything to do with ministering to the mineral needs of man, or that he merely regards it as a drug capable of acting on the whole family of infecting agents—that is, on the pathogenic bacteria. In the last two lectures he states that the action of this new compound has been instrumental in effecting a reduction in the mortality due to pneumonia. The methods of analysis described for the estimation of mineral matter are elaborate and evidently exact.

What to Eat and Drink. By CHARLES HYATT-WOOLF. London: The Gutenberg Press, Limited. 1901. Pp. 152. Price 1*s.*—For the most part this book consists of a series of articles reprinted from *Science Siftings*, of which periodical the author is editor. In many instances the analyses do not convey much information, as, for example, that of tobacco, of Yorkshire relish, or of certain cough specifics. In the analysis given of certain wines the author falls into the fallacy of recording the percentage amount of constituents to the fourth decimal place. We are perfectly certain that there is no method of analysis known which will record exactly the one-ten-thousandth part of a constituent in a hundred parts of the substance. The title of the book, "What to Eat and Drink," can hardly relate to at least two of the articles described—namely, tobacco and kelpion (a stainless iodine compound).

Arsenic. By J. ALFRED WANKLYN, M.R.C.S. London: Kegan Paul, Trench, Trübner, and Co., Limited. 1901. Pp. 106. Price 2*s.* 6*d.*—Mr. Wanklyn in this book censures the commission of experts appointed by the Manchester Brewers' Central Association, Professor Delépine and a few others, for their conduct in connexion with the recent epidemic of arsenical poisoning by beer. "Since the year 1864 some branches of chemical analysis have decayed in England. The following passage quoted from the report of the commission of experts appointed by the Manchester Brewers' Central Association to investigate the circumstances of the arsenical beer poisoning affords a curious example." The passage referred to relates to the adoption of the Reinsch test. The count which Mr. Wanklyn sets forth against Professor Delépine is that he stated that Marsh's test is inapplicable to beer which had not been previously treated so as to break up the organic matter, and Professor Delépine's knowledge of the test, Mr. Wanklyn ventures to think, was not derived from Marsh's original paper, "but must have come second-hand from some inaccurate text-book." And so the committee of experts are wrong, Professor Delépine is wrong, and everybody else is wrong who disposes of Marsh's test in favour of Reinsch's test. We quite agree with Mr. Wanklyn that there is still some mystery about the nature of the poisoning which we hope will be cleared up by the Royal Commission, and it is also possible, as Mr. Wanklyn believes, that the arsenic existed in a hitherto unknown combination, perhaps an organo-metallic one. The process of fermentation may have evolved a new arsenical compound more poisonous than arsenic itself. The book contains Marsh's original paper which was read at a meeting of the Society of Arts in 1836. In this account there is an obvious error in stating that arseniuretted hydrogen has precisely the same *colour* as arsenical fumes.

JOURNALS AND MAGAZINES.

The Journal of Anatomy and Physiology. Conducted by Sir WILLIAM TURNER, F.R.S., D. J. CUNNINGHAM, F.R.S., G. S. HUNTINGDON, M.D., A. MACALISTER, F.R.S., and J. M'KENDRICK, F.R.S. Vol. XXXV., Part 3. April, 1901. London: Charles Griffin and Co., Limited. 8vo. Price 6*s.*—The articles contained in this number of the *Journal of Anatomy and Physiology* are: 1 On the Topographical Anatomy of the Abdominal Viscera in Man, especially the Gastro-intestinal Canal, by Christopher Addison, M.D. Lond., Professor of Anatomy, University College, Sheffield, with three plates and two tables. In this article useful tables show the average positions of the parts in the ileo-colic region of the large intestine and of the solid viscera. 2. Notes on the Hairslope in Man, by Walter Kidd, F.Z.S. The direction of the hair in different parts of the body, as the chest, back, legs, arms, and head, is carefully given. The author of the article considers that in man the direction of the hairslope is in many regions determined largely by external forces and by habits peculiar to man. 3. Abnormal Veins in the Frog, by Thomas W. Shore, M.D. The veins described are an unusual renal portal vein, a vein connecting the renal portal and the pulmonary, mesenteric, splenic, and hæmorrhoidal veins connected to the left lung, and an innominate vein. 4. A Contribution to the Morphology of the Human Urino-genital tract, by D. Berry Hart, F.R.C.P. Edin., with two plates. 5 Contribution to the Pathology of the Bladder and Ureter; Extroversio Vesicæ and apparent low Implantation of the Ureter End, by D. Berry Hart, M.D., F.R.C.P. Edin., with a plate. 6. Osteology of the Penguins, by R. W. Shufeldt, M.D., C.M.Z.S., with a plate. 7. Notes on the Osteology of Scopus Umbretta and Balæniceps Rex, by R. W. Shufeldt, M.D., C.M.Z.S., with a plate. 8. The Joint in a Fowl's Tongue and its Vocal Function, by W. Ainslie Hollis, M.D. Cantab. Dr. Hollis considers that this structure is the effective agent in producing the "cluck" of the hen. 9. On the Notches and Fissures of the Spleen and their Meaning, by F. G. Parsons, F.R.C.S. Eng., Lecturer on Anatomy at St. Thomas's Hospital. The author of the article considers the notches of the spleen to be mere crumplings of the organ due to its growth and to the pressure of the surrounding viscera. They often correspond to the position of vessels. Lastly, we find the Proceedings of the Anatomical Society of Great Britain and Ireland for February, 1901.

Analytical Records

FROM

THE LANCET LABORATORY.

TABLOID, APOMORPHINE HYDROCHLORIDE AND STRYCHNINE HYDROCHLORIDE.

(BURROUGHS, WELLCOME, AND CO., SNOW-HILL-BUILDINGS, LONDON, E.C.)

THIS tabloid is intended for the convenient preparation of a solution of the hydrochlorides of apomorphine and strychnine for hypodermic purposes. Apomorphine is used as an emetic, but its administration is sometimes followed by considerable depression and even collapse. This objectionable effect is avoided by the addition of strychnine hydrochloride, the combination thus providing an emetic free from depressing effect. Since the employment of a fresh solution is essential the tabloid is very useful to that end.

GRAPE LIQUEUR BRANDY (SPANISH).

(WILLIAMS AND HUMBERT, 17, MINCING LANE, LONDON, E.C.)

We have frequently drawn the attention of the profession to the excellent brandy now being introduced into this country from Spain. Not the least important point about this brandy is that it is pure grape spirit duly matured in wood. It has been said that there can be no question as to whether Spanish brandy is the produce of the juice of the grape, for grape juice is the cheapest liquid in Spain next to water, and thus the failure of the grape crops in the celebrated environment of Cognac through the devastation of the phylloxera has been the opportunity of the wine-grower in Spain. Since the failure of the French vineyards suspicion has for a long time past been cast upon the consignments of brandy called "Cognac" coming into the country, and very naturally so. There can be no doubt, however, of the genuineness of Spanish brandy imported in case. It is a pure grape spirit uncontaminated with spirit from potatoes, maize, or other foreign materials. Hence Spanish brandy when duly matured may be confidently recommended for special medicinal purposes. The sample before us is an excellent type, possessing an aroma and bouquet resembling closely the fine liqueur champagne brandy imported from the Cognac district over 20 years ago. Our analysis gave the following results: absolute alcohol, by weight 42 29 per cent., by volume 49 81 per cent., equal to proof spirit 87 29 per cent.; acidity reckoned as acetic acid, 0 09 per cent.; extractives, 0 32 per cent., and ethers, 2 8 parts per 10,000. The last result recording the amount of ethers in the spirit is characteristic of a true grape brandy. The value of genuine brandy that is a pure wine distillate resides in its restorative and stimulating properties which are not possessed to anything like the same degree by etherless brandy, and the spirit derived from cereals is invariably free from ethers and certainly from the peculiar ethers of wine. We are glad to note that the above wine-shippers are introducing this excellent brandy direct in cases from Spain, a proceeding which guarantees it as a genuine product and which avoids any risk of it being tampered with in bottling. By this desirable arrangement the medical man may know for a certainty that the brandy he uses or recommends is genuine grape spirit, which is, moreover, not inferior as regards flavour and bouquet to the Cognac of the "seventies."

BEAMISH'S STOUT.

(GENDALL AND CO., 34, NORFOLK STREET, LONDON, W.C)

A plan has been adopted in regard to the bottling of this stout which may be commended. It is bottled by a special process whereby fermentation practically ceases by the time the malt liquor reaches the bottle. The result is a stout without any objectionable excess of carbonic acid gas. The taste is therefore mild and free from the sharp taste of highly carbonated liquors. On pouring out the stout into a tumbler it "creams" rather than effervesces. We understand that the specimens which we examined had been kept for more than 12 months—that is to say, the stout was bottled over a year ago. Our analysis was as follows: malt extractives, 5 36 per cent.; mineral matter, 0 28 per cent.; alcohol, by weight 4·94 per cent., by volume 6 17 per cent., equal to proof spirit 10·81 per cent. The stout was in good, sound condition.

MEAT POWDERS (BEEF, CHICKEN, AND TURTLE).

(H. J. DUNN, 110, BRIGHTON-ROAD, SOUTH CROYDON)

There should be a great future before these very interesting nutritive preparations. They present the entire qualities and properties of the respective meats from which they are prepared, the process of preservation being effected without altering the chemical or physical condition of the constituents mainly by drying the fresh meats in the cold. The result is a fine dry powder which may be used for preparing a juice containing albumin in the same condition as it occurs in raw fresh meat or the preparation of a really nourishing soup or "tea." The advantages thus gained are very obvious, and especially in the sick room. Thus the rapidly restoring effects of a raw meat juice may be obtained by simply infusing the powder in cold water and straining. On boiling the clear liquid a large part of its albuminous contents coagulates, just as in the case of boiling the white of an egg. We found that in this way the turtle powder yielded nearly 10 per cent. of coagulable albumin, the beef powder 6 per cent., and the chicken powder 7 2 per cent. Nor are the preparations deficient in the soluble and stimulating constituents of meat, these amounting to from 10 per cent. to over 15 per cent. The extraneous fat is carefully removed. We append our analyses of the three preparations. Beef powder: moisture, 7·48 per cent.; ash, 7·78 per cent.; proteids, 67·14 per cent.; and fat, 17 60 per cent. The cold water solution of this powder gave the blood spectrum which shows conclusively that the original condition of the meat is successfully preserved, the process in no way altering the condition of the nutritives, a condition so often essential in the feeding of the sick. Chicken powder: moisture, 7 61 per cent.; mineral matter, 7 37 per cent.; proteids, 77·42 per cent.; and fat, 6·60 per cent. This, like the beef powder, yielded a cold water solution of coagulable albumin, the clear fluid on boiling yielding a bulky albuminous coagulum. Turtle powder: moisture, 3 68 per cent.; ash mineral matter, 13 75 per cent.; proteids, 76·17 per cent.; and fat, 1·40 per cent. The turtle powder yielded nearly 10 per cent. of coagulable albumin, a result which largely explains the nutritive properties of this "fish, flesh, and fowl." The flavours both of the cold extracts and of the soups were preserved to a remarkable degree. We can speak very favourably of these preparations and no proof is needed that they are a great advance upon mere extracts of meat. They present all the nourishing constituents of the meats from which they were obtained and the flavour of the fresh meat is in no way sacrificed. Further, they offer a convenient and effectual means of preparing at a moment's notice either a nourishing raw meat juice or a nutritive soup or "tea." They should prove especially valuable in the sick room, where a juice or a soup may be immediately dispensed by this means—that is to say, raw or cooked meat can be administered, as the case may require. The powders would form also excellent adjuvants to other foods, raising their nutrient value to a powerful and certain degree. We have carefully considered the details of the process by which these meat powders are prepared, and the steps taken to retain the natural flavour of fresh raw meat and to preserve the nutrient strength of the original material unimpaired are as remarkable as they are ingenious.

New Inventions.

"DARK ROOM" FOR OPHTHALMOSCOPY AND LARYNGOSCOPY.

MR F. DAVIDSON of 140, Great Portland-street, W., manufactures a portable "dark room," which will in many cases be very serviceable in ophthalmoscopic and laryngoscopic examinations. In principle it somewhat resembles an ordinary photographic camera, having a bellows body, with the end carrying the lens removed. It consists essentially of two square mahogany frames having each a clear internal aperture of about 15 inches square. When in use these frames are vertical and are connected by the usual bellows arrangement; one of them is fixed to a wooden base and the other slides upon it so that the box or chamber formed by the bellows body may be adjusted to any length varying from eight inches to three feet. For retinoscopy it will usually be opened out to the full extent; for indirect examination a less elongation will be convenient. The surgeon looks in at one end and the patient at the other, a black curtain falling over the shoulders of each so that extraneous light is totally excluded. A lamp with a separate plano-convex condenser having universal motions is placed over the patient's head and in front of the surgeon there is a support on which the ophthalmoscope may be placed. The neutralising lenses for use in retinoscopy are set in a toothed wheel rather less than seven inches in diameter, which the surgeon can rotate with the utmost facility by means of a long brass rod inserted into the axis of a pinion. This wheel or dial carries 26 lenses, varying from + and – 0 5 to + and – 8. When opened for use the "dark room" is placed on a table, on which it stands quite firmly. Its special feature is its portability, for the bellows collapse, the base being hinged folds up against the ends, and the whole packs into a canvas cover so that it can be easily carried in one hand like a portmanteau. The price is 10 guineas complete, or eight guineas without the revolving dial carrying the lenses.

MEDICAL SICKNESS AND ACCIDENT SOCIETY.—The report of the Medical Sickness and Accident Society states that during the year 1900 the number of members had increased to 2006, and the financial results of the year's working were very satisfactory. The funds increased by £11,379, almost the largest amount in any year's working, and, as no new annuity or life assurance business has been transacted by the society for some years, this shows the sickness business to be in a very healthy condition. The society is strictly confined to registered members of the medical profession, and is conducted on purely mutual principles. In 1900 £8250 were disbursed to the members as sickness benefit, being the largest amount ever paid away for this purpose in one year, but nevertheless, well under the expectation. The funds now amount to £143,553. Continuous sickness pay until the age of 65 is allowed in cases of permanent incapacity, and over a dozen of the members are under this arrangement drawing a permanent provision.

THE LANCET.

LONDON: SATURDAY, JUNE 1, 1901.

The Government and the Medical Profession.

As we briefly announced last week, Dr HENRY WARD IRVINE of Birmingham has been selected by the Education Department to be one of His Majesty's Inspectors of Schools The circumstances of this appointment presented features which made it inevitable that attention should be directed to it in Parliament, and the debate which accordingly arose was not directed either against the political probity of the Colonial Secretary or against the personal character of Dr. IRVINE At least such is our opinion, and certain it is that things far harder than any that were said last week in Parliament concerning Dr IRVINE'S appointment can now be said concerning the attitude of the Government on the matter. Dr. IRVINE accepted the appointment of medical officer to the Birmingham Consultative Institute at a time when the *medical profession* in Birmingham considered that the Institute was promising to give to the public professional facilities that it was not in a position to give The Institute advertised Dr IRVINE as its medical officer in a manner which was unprofessional. The matter was brought before the General Medical Council at the winter session of last year, and that body, while finding the charge proved against Dr. IRVINE of unprofessional conduct, treated him with all consideration, not removing him from the Register, but giving him a period of six months in which he could think over his position In the interval Dr. IRVINE, while presumably purging himself of unprofessional conduct, has been given a Government appointment, an appointment which he is no doubt well qualified to hold, but which as a matter of fact hardly ever is held by a medical man Mr McKENNA, M P., did well to bring the affair to the notice of the House of Commons, and whatever his motive for doing so may have been, it is absurd to say, as certain newspapers devoted to party politics have said, that only a malignant desire to damage Mr. CHAMBERLAIN could have been at the bottom of his action The importance of the questions involved forms an ample justification of any publicity that may be given to this subject.

Mr CHAMBERLAIN'S conduct was not in question, but as he took it upon himself to assume that it was, we may say that his interference in the matter did him little credit and reflected badly upon the Government whose attitude we suppose must be gathered from that of the Colonial Minister Mr. CHAMBERLAIN said that he had never heard of Dr. IRVINE even by name, but that he knew him to be a gentleman of great professional reputation—somewhat irreconcilable statements, made more difficult to dovetail by the fact that Mr. CHAMBERLAIN proceeded to give an account of Dr. IRVINE'S relations with the Birmingham Consultative Institute, with the medical profession of Birmingham, and with the General Medical Council, which though inaccurate was clearly inspired by some knowledge. In Mr. CHAMBERLAIN'S opinion Dr. IRVINE had only infringed the "trade-union rule" of the medical profession. He added that he was not responsible for the appointment which was made by the Lord President of the Council and the Vice-President The Vice President of the Council, Sir JOHN GORST, upon whom the responsibility of defending the appointment now devolved, said that Dr. IRVINE was chosen because *of his peculiar qualifications for the post* by himself and the President of the Council, the Duke of DEVONSHIRE, who had not heard of the charges of unprofessional conduct brought before the General Medical Council against the candidate for Government employment. While it was singular in Mr. CHAMBERLAIN to be able to give a sketch of the professional career of Dr IRVINE of whom he had never heard, it was careless or cynical of Sir JOHN GORST to plead ignorance of just those antecedents of Dr IRVINE which were actually contained in official information supplied to the Privy Council on the ground that neither the Duke of Devonshire nor himself had leisure to read the reports of the General Medical Council. The General Medical Council exists for the maintenance of proper relations between the medical profession and the public under the Privy Council. When the General Medical Council saw that it was a duty to the public to caution Dr. IRVINE as to his tenure of a certain post, all the proceedings were duly sent to the Privy Council; and if Dr. IRVINE had desired to appeal against the action of the General Medical Council it is to the Privy Council that his appeal would have been directed. Yet the Lord President of the Privy Council and the Vice President, while Dr IRVINE is under the ban of the General Medical Council, select him for a much-coveted Government appointment. This is to administer a public slap in the face to the disciplinary body of the medical profession while engaged in efforts to keep the roll of the profession pure and the standard of medical ethics high.

Our profession is not aggressively political, but it is one that cannot be neglected or flouted by politicians with impunity, for it deals with human interests and social and sanitary conditions that affect greatly the welfare of the nation. Moreover, it has the political influence belonging to men of general and special education, who have chiefly themselves to blame if this influence is not considerable. We do not pretend to say to which side the political bias of the medical profession leans, but it is safe to allege that it is largely conservative in its respect for good precedent, while it has that admixture of progressiveness which comes from contact with the revelations of ever-advancing science. If the medical profession is estranged from the Government in any degree more than it was when they re-entered into office—and we have reason to think that it is so estranged—they have only to thank themselves for the position. They have not acted up to the measure of their strength, as we have on previous occasions considered it right to point out On the vaccination question they yielded feebly, and they have since broken a promise to bring in legislation requiring revaccination. They lost the opportunity, offered by the Companies Bill, of altering the law so as to prevent any lay amalgamations from being used for covering unqualified practitioners in medicine. They dealt with the midwives question in a completely unsatisfactory manner. A valuable measure to amend the lunacy laws and a bill to improve the position of medical officers of health have both failed to get into the statute book through want of Government support, and a Medical Acts Amendment Bill has had to be withdrawn. This is not a good record. The Government have shown themselves to be out of touch with right medical feeling; and during the debate upon Dr. IRVINE'S appointment the two members of the Government who spoke emphasised their aloofness in a manner that must have been evident to all our readers. Mr. CHAMBERLAIN stigmatised the endeavours of the Birmingham medical men to maintain a high standard of professional conduct as trade unionism. Sir JOHN GORST said that the Lord President of the Council and the Vice-President had no leisure to read the reports of the proceedings of the General Medical Council. Mr. CHAMBERLAIN might take the trouble, before he again discusses medical ethics, to learn something of the aims and hopes of a self-respecting profession; and he must seek outside the Birmingham Consultative Institution for information. The Duke of DEVONSHIRE might vacate his office in favour of some one who could find time to discharge its duties. And we trust that Sir JOHN GORST, when next he looks among our ranks for an official to fill a place in the Education Department, will not feel compelled to select anyone in disfavour with the General Medical Council.

Influenza as a Factor of Recent Mortality in Chicago.

WE have on several occasions drawn attention to the most instructive bulletins issued from the Chicago Health Department. These publications are issued monthly and the amount of care and study involved in their production must be immense and reflects the greatest credit on the responsible persons, both writers and editors. In the number for March of this year is a leading article on "Influenza as a Factor of Recent Mortality." That the mortality from certain diseases, notably those affecting the respiratory system, rises greatly during an epidemic is a fully-recognised fact, but when we study the actual statistics we are made more fully aware of the ravages inflicted on the human race, directly or indirectly, by influenza. Writing in Professor CLIFFORD ALLBUTT'S "System of Medicine" in 1896 Dr. J. F. GOODHART says: "The permanent home of influenza, if one there be, is not yet absolutely certain. The west of Russia seems on the whole to be its most likely source. ......" It is perfectly true that in 1889 a great pandemic of influenza began, but since that time we are gradually becoming unpleasantly aware that influenza is not a chance visitor, but that it has become one of the most common diseases in this country, frequently assuming epidemic form, and having a marked effect on the mortality returns.

The article to which we have above referred commences with the remarkable statement: "Pneumonia has displaced the 'Great White Plague'—pulmonary consumption—as the principal cause of death in Chicago during the last ten years. In the previous half-century consumption had levied the heaviest toll on human life in this city, but in the decade 1891–1900 there were 9 per cent. more deaths from pneumonia than from consumption." The exact figures are then given, showing that between 1851 and 1890 inclusive, during which period deaths and their causes were recorded with increasing accuracy and fulness, there were 25,719 deaths from consumption and 16,577 from pneumonia; between 1891 and 1900 inclusive there were 22,957 deaths from consumption and 25,228 deaths from pneumonia—2271, or 9 per cent., excess of deaths from pneumonia. Taking a survey of other figures that are given the result shows the extraordinary increase of nearly 46 per cent. in proportion to population and of more than 50 per cent. in the actual number of deaths from pneumonia in the last over the previous decade. Doubtless other causes than influenza contributed towards this great increase. Death-rates of pneumonia increase considerably with advancing age, and some part of the accession in Chicago is unquestionably due to the increasing age of its population; but careful study of the statistics given in the "Bulletin" plainly shows that the augmentation of the pneumonia mortality in Chicago during the last decade is not due solely or chiefly to this cause. The baleful effects of influenza, however, are well shown in the following table:—

—	1889.	1890.	1891.
Total deaths all causes	16,946	21,856	27,754
Rates per 1,000 of population	18·11	19·87	23·92
Total deaths from pneumonia	1170	2073	2698
Rates per 10,000 of population... ...	12·5	18·8	25·0
Total deaths from consumption... ...	1489	1972	2120
Rates per 10,000 of population... ...	15·9	17·9	18·3
Total deaths from bronchitis	816	1189	1495
Rates per 10,000 of population... ...	8·7	10·8	12·9

The total deaths from all causes in 1891, the second "influenza year," are the highest number ever recorded in the history of the city up to date and are nearly one-third greater in proportion to population than in 1889. The consumption death-rate increased 15 per cent., the bronchitis rate one-half, and the pneumonia rate exactly doubled in the two years. Deaths from nephritis and from heart diseases also markedly increased, but not to the same extent as in the later years of the decade. The author of the article to which we are referring makes the interesting comment that the permanent increase of the mortality from consumption did not become marked until the fifth year of the influenza period. We agree with the explanation that is offered of this fact—namely, that pulmonary tuberculosis is a chronic and pneumonia an acute disease. Lesions of the mucous membrane of the nose, throat, and air-passages in the prevailing catarrhal bronchitis of influenza and of the air-cells in pneumonia rendered the soil suitable for the invasion of the tubercle bacillus, while the characteristic prostration of influenza and consequent impaired vital resistance favoured the development and activity of the bacilli which entered the system.

The article then refers to the bacteriology of influenza and rightly insists that its early recognition is the necessary first step to any restriction of its spread We cannot agree with the author, however, when he states that "the way to fight influenza is through the culture tube and the microscope" The high mortality that may ensue during an epidemic of the disease and the deplorable sequelæ that may never be completely recovered from are accepted facts, but too great a tendency has of late years been evinced to trust to bacteriological investigation rather than to clinical observation; the former is an immense aid to the latter, but must not be suffered to usurp its place The early diagnosis of influenza is of importance, and still more so is the adoption of means to prevent its spread In cases which present anomalous symptoms or run an unusual course the recognition of the pathogenic bacillus is of the utmost value, and we believe that for such purposes the laboratory facilities now so generally existing are not sufficiently made use of and many cases thus escape early detection, and the means of preventing the spread of the disease not being used infection of other persons is very likely When the disease, however, occurs in epidemic form the prevention of its rapid spread is most difficult, and it is only by insistence by practitioners on isolation that its diffusion can be stayed The quarantine period has not been definitely fixed and patients are apt to mix again with the world at large in pursuit of their ordinary avocations at too early a period and consequently again become centres of infection

◆

Administration in Irish Lunatic Asylums.

IN a leading article on April 13th last the *Sligo Independent* speaks in no uncertain tone as to its regret that the "high reputation of the Sligo Asylum should have been sullied by the brutal conduct of one of the attendants—a man named GAFFNEY—who savagely attacked a quiet and inoffensive patient and injured him most severely" The conduct of the Asylum Committee in dealing with this individual is almost incredible, and we feel it to be our duty to place the case somewhat circumstantially on record

An inspector of lunatics held an inquiry on oath, and from the official report as recorded in the *Sligo Independent* the facts of the case show that on April 2nd when the resident assistant medical officer was going his rounds he found the patient in question not walking about as was customary with him but sitting sobbing on a chair On being questioned the patient said that the attendant had beaten him, and the resulting injuries were found to comprise bruising of the left ear, bruising of the lower lip, the inner surface being cut by the edge of the teeth, a bruise of the right temple, bruising and tenderness over the left lower ribs and the lower part of the abdomen; severe bruising of the left thigh, the skin being removed; and a bruise on the right thigh Two patients corroborated the patient's statement and an attendant swore that he saw GAFFNEY hit and kick the patient GAFFNEY admitted having struck the patient, his only reason for the assault being that he was in the way when the ward was being cleaned up The report goes on to say that the offence was aggravated by the fact that the patient was a harmless, quiet, and most inoffensive man who, apart from his symptomatic restlessness, gave no trouble whatever The inspector gave it as his opinion that the services of the attendant ought to be dispensed with, on the ground that any person who would wilfully strike a patient, or had so little control over himself as to do so in a fit of temper, was utterly unsuited to be an attendant on that afflicted class of persons whose safety and well-being depend so much on the character and conduct of those who are placed in charge of them He further urged that if the committee were to condone such an offence, the asylum, instead of being, as it should be, a haven of refuge for the insane, would become a place to be feared and dreaded and the confidence of the public would be shaken in its management, while the ratepayers would become distrustful of the care and treatment which the inmates received In spite of the cogent utterances of the inspector the committee decided to retain the services of GAFFNEY One member gave it as his opinion that it was not a bad case, otherwise he would have dismissed him at once, and in any case, he thought that the retention of the attendant might be more effective than his dismissal would be

This decision appears to have been arrived at by the Leitrim members of the committee, all the Sligo members of the board having left to attend another meeting when the report on GAFFNEY'S misconduct came up for discussion The *Sligo Independent* refers to the probable great surprise of the Sligo members when the facts became known to them and it concludes its article in the following terms "We would not insult their humanity by even hinting that they would condone an offence against an afflicted and inoffensive man whose mental darkness made him the defenceless victim of an infuriated attendant" This out spoken condemnatory expression of feeling on the part of the local press cannot fail to find itself re echoed in the minds of all right-thinking, humane, and unbiased persons There must be some local or personal reason to account for this frustration of the well directed efforts of the inspector to maintain the reputation of the asylum But while the incident is one fortunately not of frequent occurrence, it is one from which a significant moral may be drawn in view of an agitation that has for a number of months been going on in official lunacy circles in Ireland having reference to the management and treatment of chronic cases of insanity A circular of the Local Government Board for Ireland with respect to the establishment of auxiliary asylums for harmless lunatics, idiots, and imbeciles led the Cork Asylum Committee to propose the utilisation of a disused workhouse at Youghal for this purpose, with such enlargements and adaptations as might be considered necessary and with such internal fittings and medical and other equipments as the circumstances of the case seemed to require, together with an increased cost of maintenance as compared with that expressly mentioned in the Local Government Act Any differences of opinion between the committee and the lunacy officials at Dublin Castle on these various matters would appear, from correspondence and statements in the *Cork Daily Herald* of Feb 11th and 23rd and in the *Freeman's Journal* of April 13th, to have been not absolutely insurmountable, or at all events not hopelessly impossible of authoritative decision one way or another. But when the Cork Asylum Committee decided that their auxiliary asylum for several hundreds of lunatics, idiots, and imbeciles was to be placed under lay resident superintendence we are not at all surprised to find that the lunacy authorities—the lunacy inspectors, in fact—recognised therein the invasion of a principle which they felt it to be their duty to uphold in the true interests of the insane—viz., that the immediate management and care, as well as the treatment, of any considerable number of mentally diseased and disordered beings in an asylum ought to be in the hands of a resident medical superintendent. Are we to take it that by a transference from Cork to Youghal or from a district asylum or workhouse to an auxiliary asylum these unfortunate members of the community leave behind them their brain lesions and their nerve lesions? Is it no longer the case that their bodily organs and functions, their passing humours, eccentricities, restlessnesses, demented helplessnesses, require that close supervision and individual attention which a resident medical officer is able to give, but which cannot possibly be expected to result from the daily visit of a non-resident physician, however experienced and careful? The latter might very properly see to the hospital sick, but who will ask him to make a daily inspection of all the inmates whereby alone he can have an opportunity of observing in their earliest stages new deviations and further progressions in conditions that had become more or less quiescent It is, for instance, a matter of doubt whether a merely visiting physician, who cannot be expected to know the habits and the characteristics of conduct of the bulk of asylum inmates, would have happened to detect during his visit the unusual condition of the patient to whose cruel treatment we have called attention. We do not wish to lay stress upon an individual case beyond pointing to it as an illustration of the needs as well as the risks that must attend the administration of an asylum containing only harmless patients, if ever we can bring our minds to regard idiots and imbeciles as generally belonging to this class. We are unable to do otherwise than to give our support to the lunacy authorities in Ireland in resisting the introduction of lay superintendence under the circumstances to which we have referred and we are not surprised that the inspectors would rather counsel the building of annexes to the district asylums where the immediate supervision of a responsible resident medical officer would not be denied to hapless lunatics under all the varying conditions to which their diseases render them liable and under the risks which in asylum life are associated with their restlessness and enfeeblement of mind.

We cannot conclude this article without reference to the opinions expressed by the Bishop of Ross, a member of the Cork Asylum Committee and the apostle of lay management in auxiliary asylums. In a letter to the *Cork Daily Herald* of Feb. 11th he admits that there is justification for the residence of medical officers in main or district asylums. He then goes on to speak as follows: "But what purpose will they serve among idiots and imbeciles? How they are to be employed surpasses common comprehension: the problem must be solved by the wisdom of the Lunacy Office. Will those highly skilled medical gentlemen be engaged in the vain task of infusing intellect into those whom God Almighty created idiots, or in the unsavoury task of looking after the beds of those poor creatures many of whom are of uncleanly habits? *It would seem to me that a few strong, vigorous women, neither squeamish nor over-refined, would be more necessary and efficient officers.*" The italics are ours, and we would ask whether this corollary of the "lay superintendent" idea is to be the trend of twentieth century science and humanity, and whether it is a system of treatment and administration that is likely to meet with the approval of the relatives and friends of the chronic insane or of the public generally.

Annotations.

"Ne quid nimis."

PROTRACTED GESTATION.

THE degree to which the duration of pregnancy can be prolonged has always been a matter of great interest. A very remarkable case of this kind is recorded by Mr. G. H. Hames in THE LANCET of May 25th, p. 1496, in which 320 days had elapsed from the last day of the last period to the day of the child's birth. Estimating the duration of pregnancy from the last day of the last period is always open to the fallacy that the patient may have become pregnant either immediately after the cessation of the last period or just before the period which failed to appear. If, however, we examine the data obtained from observations upon animals in which the date of a single coitus can be accurately determined we find very wide differences in the duration of gestation. Spencer and Tessier from observations upon 1303 cows found that the calves were dropped from the 253rd to the 321st day after coition—a difference of 68 days. Similar observations carried out by St Cyr upon mares showed a difference of as much as 87 days between the duration of the shortest and the longest pregnancy. In the case of the human subject statistics based upon a single coitus are always untrustworthy, but Dr. Nunnez-Ressié has recorded the case of a girl who gave birth to a child 317 days after she had been raped. Large numbers of cases of prolonged gestation have been recorded both by the old medical writers and in many of the modern works on jurisprudence. Joh. Johnston quotes Paschal as relating an instance of birth after a pregnancy of 23 months, Aventium one after two years, and Mercurialis one after four years' gestation! A case was decided in the Supreme Court of Friesland in 1634 in which a child born 333 days after the death of the husband was pronounced legitimate. As Gould tells us the Parliament of Paris was gallant enough to come to the rescue of a widow and save her reputation by declaring that a child born after a 14 months' gestation was legitimate. Campbell says that Simpson met with cases of pregnancy lasting 319, 332, and 336 days, while Meigs had seen one of 420. Jaffe describes an instance of the prolongation of pregnancy for 365 days in which, as in Mr. Hames's case, the weight and measurements of the child appeared to correspond to the degree of protraction. The civil code of France limits the longest period of the legitimacy of an infant to 300 days, the Scottish law to 300 days, and the Prussian law to 301 days. We may safely assume that the French law in fixing the limit of gestation at 300 days is well within the normal duration of pregnancy, and it is difficult to accept as authentic most of the recorded cases in which the gestation, reckoning from the last day of the last period, is said to have been prolonged much beyond this period of time. There can be little doubt that many of the older instances of very protracted gestation are to be explained by the retention of the fœtus in cases of extra-uterine gestation. A very interesting medico-legal point has been raised in some of these cases as to when the 300 days is to be counted from Is it to be reckoned from the exact hour of the marriage, from the hour of the death of the father, or the hour of the separation of the parents? or is it to be counted by legal periods of 24 hours In a case which came before it the Court of Angers decided that the duration of pregnancy should be reckoned from the moment of the death of the father. The Court of Cassation, however, upset this judgment and laid it down that the word "jour" signified a period of 24 hours, counting from midnight to midnight. In the particular case in question the father died on March 19th, 1866, at 2 A.M., and according to the Court of Cassation the period of 300 days commenced at midnight on the same day. The widow was confined on Jan 13th, 1867, at 8 A.M., and the 300th day, therefore, expired at midnight of the same day. Another interesting medico legal question which might arise is whether it would be possible for a woman to delay her delivery until the expiration of the limit of 300 days. In a case of this kind in which the wife wished to give her husband grounds for bringing an action against her the medical man is said by the administration of laudanum to have succeeded in delaying the birth of the child from the 298th to the 301st day.

PETROLEUM INCANDESCENT LIGHTING.

IT would seem almost idle to revert to oil as an illuminant when the great advances that have been made with both gas and electricity are considered, but recently a system of lighting by petroleum has been so successfully inaugurated in some of the London streets as to appear a reproach to existing gas lighting systems and the electric arc light The system that we allude to, which is very well illustrated in a recent installation along the whole length of Portland place, depends upon, first, the automatic vaporisation of petroleum oil, secondly, on the mixture of this oil with air, producing a flame like the Bunsen or atmospheric flame, free from a tendency to deposit soot, and, thirdly, on the impingement of this flame upon a specially made Welsbach mantle of the rare earthy oxides The light produced excels both the electric arc light and the incandescent gas light in its diffusive power, while its brilliancy may be almost without limit Its value for public street lighting is at once evident where installations have already been made and the contrast with gas and the electric arc is most favourable, while the cost is, as might be expected, much less so long as oil is as cheap as it now is. Moreover, a feature of the new system is—and we most heartily welcome this feature—that it dispenses with the "grubbing-up" of London streets The persistent tearing up of London streets is a serious matter, and an expensive matter, too, which may be placed as a very telling item to the account of both gas and electric lighting. With the new system of petroleum incandescent lighting, which is the invention of Mr. Arthur Kitson, M E, there is no necessity to dig down to mains in order to establish connexions Each lamp contains its own modicum of oil, the oil being contained in a strong metal cylinder under a slight pressure of air. The oil is forced into the cylinder by means of a force-pump and the air at the top in a similar way. The pressure of air simply serves to force the oil through an exceedingly small tube to the burner. The metallic tube is no thicker than the wire used for electric lighting, the thickness varying from one-sixteenth of an inch to a quarter of an inch. It is in reality a capillary tube. The tubes may be placed in a wooden moulding in the same way as are electric wires, and one cylinder or reservoir will furnish oil through these tubes for any number of lamps. The trouble of keeping the reservoirs charged and the lamps in going order is no more than that encountered by the postman in clearing letter-boxes. In some cases the renewal of oil or air may be needed daily, but in others only weekly. The oil is forced up to the burner where it is vaporised automatically. At the same time air is mixed with the oil by injection, producing a powerful atmospheric flame. It is said that the Kitson lamp gives more light than the so called 2000 candle-power electric arc lamp and is more reliable at less than half the cost The ordinary street lamps give 1000 actual candle power, but lamps are made which give a light from 50 candle power upwards. We are not aware that it is proposed to apply the system to domestic lighting, in which case it would be especially important to ascertain whether the system is satisfactory from a hygienic point of view. We are not informed as to whether the combustion of the oil is perfect or whether the lamp is free from smell. But a system which can light the City of London for less money than is now paid annually for tearing up the streets and repairing the mains, and which, moreover, gives a light of very high standard of diffusive power, is calculated to bid all lighting authorities to pause before increasing the undoubted nuisance and expense of a chronic upheaving of pavements and roadways. We understand that the light is very penetrating during fog and on this score far excels other systems Some interesting experiments with the most surprising results are being tried in lighthouses The system is, of course, in its infancy, and we have yet to learn how far it can guarantee success in the long run. But that it opens up many interesting possibilities in regard to public lighting is certain. Its application in the country should prove a very great advantage. We have been very much impressed with the installations which we have seen in London, notably in Portland-place and in the Marylebone-road opposite the Great Central Hotel. It would be odd if it should prove that this system of oil lighting should supersede existing systems of electric and gas lighting or even acetylene gas. However, it is often the case that one line of promised advancement, as, for example, electricity, becomes so fascinating that the possibilities of older systems are left unstudied and undeveloped. And there can be no older system of lighting than by means of oil.

MEDICAL ADVICE IN LAY NEWSPAPERS.

THE reasoning powers of the man or woman who is able to pay a medical man's fee and yet prefers to get advice through the columns of a penny newspaper must be curiously small or unexercised. Nothing else except motives of an unwise economy, a penny-wise pound foolish method, can explain the prevalent custom of asking advice by writing the description of an illness to a man who has never seen the case and most likely never one like it. As far as the question of expense goes anyone can understand the temptation for a poor man to get for a penny advice couched in apparently the same terms as those in which a medical man would proffer it to him. Yet medical men are notably charitable, and, even apart from their charity, other considerations unfortunately reduce medical fees in many neighbourhoods to a very low figure, so that it must always be possible for the sufferer, however slender his means, to get advice from a qualified medical practitioner If even the smallest fee is beyond his reach then the patient has hospitals to fall back upon. Yet in many instances he prefers to write a description of the case to the "medical" columns of a newspaper and to receive the instructions of its adviser. The chance of such advice being good must obviously be extremely slender. To begin with, the kind of man who is willing to give advice in this way upon cases which he has never seen is not likely to possess a high degree of education. Moreover, if he were the best instructed and ablest of medical practitioners his chance of making a correct diagnosis would be smaller than those of an inferior man who had actually seen the case in question. This is an argument which might be expected to prevail upon even the lowest intelligence. Most people would hesitate to send the purchase-money for an article without seeing the article first. Yet they are willing to pay someone, of whose name and position they are ignorant, to say what is the matter with them and how they are to be cured, when the patient and his adviser have had no closer communication than that which the post affords. It is another instance, presumably, of the truth demonstrated over and over again by the success of quacks and patent "cures," that where matters of health are concerned the human being is ready to believe anything he is told. Apparently the one exception to his credulity is that he does not readily believe that men who make the study of disease the main object of their lives are more likely to treat it with success than a confident quack or an ignorant compiler of prescriptions for a lay newspaper. We do not, of course, suppose that there are many people of position in the class that supports newspaper medical advice, but with the boasted educational progress of the day this class should be much smaller than it is. Our attention has been once more directed to the matter by the indignant letter of a correspondent, himself a layman, who inclosed the medical portion of a recent issue of the *Family Herald*. Our correspondent believes that the livelihood of the general practitioner is seriously menaced by the custom of which we have been speaking. Though we deplore the practice as much as he does we do not believe that it does much harm to the medical profession, but rather that the patients themselves are in the long run the chief sufferers, having probably to correct their newspaper "medical advice" by a subsequent acquisition of the genuine article.

THE IMPORTANCE OF ASEPTIC VACCINATION.

DR. WILHELM KARL KUBIN of New York has lately read a paper before the Medical Society of the County of New York on the Importance of Aseptic Vaccination, with Remarks on Vaccination in General. The paper is published in the *Medical Record* of New York of April 6th and is well worth the study of all practitioners. So many practitioners pass through life without *seeing any serious* result from vaccination that they are apt to think it unnecessary to apply to the operation those precautions of hygiene and asepticism which they insist on in every other surgical procedure. So true is this that in an experience of 50 years or more of the medical officers of the London Small-pox Hospital they did not see from vaccinations or revaccinations further inconvenience than soreness of the arms in some cases. It is to reduce this soreness and other more serious consequences that all good practitioners feel it to be their duty in vaccinating to take pains not to insert anything but pure lymph and to watch any case carefully for a week or two subsequently to vaccination. It is scarcely necessary to say that Dr. Kubin gives the most striking proofs of the efficacy of vaccination and revaccination in protecting from small-pox. We need only instance one fact quoted by him—that in the Franco-German war, in which both armies were fully exposed to small-pox, the German mortality was only 263 men, while the French loss was 23,468, though the French army was at no time more than half the size of the German army, the difference being due to the thoroughness with which vaccination is carried out in Germany. He agrees with Dr. Brouardel in thinking that a community in which every individual has been vaccinated and revaccinated is absolutely protected from an epidemic of small-pox. But the object of Dr. Kubin's paper is to enforce the fact that vaccine lymph, even calf lymph, is by nature septic and contains numerous forms of germ life which, however harmless in most instances, are pathogenic under certain circumstances, to say nothing of manifestly pathogenic germs which may be present exceptionally. He accepts the conclusions of Koch, Copeman, Blaxall, and others that the number of such germs decreases on the addition of glycerine, even to the destruction of streptococcus, the diphtheria bacillus, and the bacilli of tubercle and erysipelas. He insists that unless due precautions are taken untoward results will occasionally follow vaccination and so keep up that absurd prejudice against it which is nowhere more discreditable than in the land of Jenner. He enumerates the principal causes of untoward results incidental to vaccination as follows: (1) impure virus; (2) abnormal or paradoxical course of the cow-pox itself; (3) improper performance of the act of vaccination, as by (*a*) unclean instruments and hands of the operator, (*b*) improperly prepared surface for vaccination, and (*c*) imperfect dressing, which will allow secondary infection; (4) neglect on the part of the vaccinator to exercise supervision and control of the patient until the time of complete healing; and (5) coincident diseases, such as scarlet fever, measles, and the like. His illustration of the possibility of all these accidents is ample and is taken from all sources—from the reports of friends, from literature, and from his own experience. Dr. Kubin prepares the skin and his instruments as carefully for vaccination as any Listerian surgeon would for a major operation. He scarifies so as to have very little bleeding and then rubs in the matter with a spatula—all, of course, being aseptic—and immediately applies his aseptic shield of which he gives the following description. "My shield consists of eight layers of gauze, each three and a quarter inches long and three and a quarter inches in width, having inclosed in the centre a wire net two inches long and one and a half inches wide with a height of one-half inch. Five aseptic strips, each one six inches long and one-half inch wide, accompany every shield, four of the strips to be used in the primary adjustment of the shield and one for reserve to be used when inspection is made. This all reaches the physician in an aseptic condition. Under this device the scab will remain undisturbed by friction of clothing and healing may go on to completion under a single shield. The shield is secured with strips of adhesive plaster. On the first inspection, should the shield be found soiled by discharge, which happens occasionally, a new shield must be substituted." In conclusion Dr. Kubin recommends that a national law should be passed in the United States for enforcing vaccination and revaccination such as exists in Germany.

THE ANNUAL TAX OF THE ONTARIO MEDICAL COUNCIL.

OUR Canadian Correspondent writes:—After the practitioner has *secured by examination* a licence to practise medicine and surgery in the province of Ontario at a cost of $100 the Medical Council, the governing body of the College of Physicians and Surgeons, demand and exact from him an annual fee of $2.00. There are about 2500 practitioners, in this province and some 700 of them have become debtors to the Medical Council to the extent of several years' assessments. In order to make these delinquents pay up the official prosecutor of the Council on April 19th addressed to each of them a circular letter informing them that their names had been erased from the Register of the College of Physicians and Surgeons and that unless they settled with the registrar within 30 days from the date of the letter they would be proceeded against like all other unregistered practitioners, thus practically putting them down in the same category as quacks. About 100 of the 700 immediately paid their assessments along with the arrears, but the remainder sent representatives to the number of nine to wait upon the Provincial Government to protest against the imposition of this annual tax. The delegation was headed by Dr. Sangster of Port Perry who is himself a member of the Medical Council and who some 10 years ago was the leading spirit in a similar onslaught upon this tax which caused no little bitter feeling in the profession at that time. The opponents of the tax claim that they receive no benefit for it at all, that the Medical Council, which is composed of 30 members, are dominated by the college men and the homœopathic body, who have a representation of 13 between them; and that the regular profession is not properly represented on the council. Should the Medical Council persist in their claim and attempt to carry out their threat no doubt times will be warm in the medical profession in this province during the coming summer months in other than a literal sense. On the other hand, the *mandamus* having been issued, those who have responded will expect the Council to go on and to prosecute. There is every likelihood of a test case being submitted to the courts for decision as to the legality of the obnoxious tax.

"SWEETS SPARKLING WITH GLASS."

WE never doubted that the revelations which we published in regard to the presence of glass in certain sweets would be received with incredulity. Further than that, our analyses have been "challenged." Couched in more temperate and courteous terms than characterised some remarks in the general press upon the subject was an article appearing in *Confectionery* of May 13th, 1901, a journal devoted to "the interests of sugar confectioners, chocolate manufacturers, and fruit preservers." In this article our annotation is reproduced in full The editorial opinion is expressed that it is a case in which, in the interests of the trade, the Confectioners' Association should take action With this we cordially agree We have reason to believe that sweets containing glass are still circulating and we therefore repeat our recommendation that the local authorities throughout the country should institute practical inquiries under the Food and Drugs Act and should prevent the sale of such dangerous articles We can afford to disregard any impugnment of our analysis. No particular skill is required to detect glass in sweets, but it is desirable that examination should be set on foot before the presence of glass is indicated by serious mischief done to the human body. We have not been able to trace the makers of the sweets in question, but we may state that the specimens were sent to us by Dr. Horace Savory of Bedford whose attention was drawn to the sweets as the possible cause of severe abdominal pain in two little children under his care. There is no doubt that the sweets were the origin of the serious symptoms and that the sweets contained sharp splinters of glass. The splinters, moreover, were not buried in the body of the sweet but inlaid on the surface. From information which we have gained, we are inclined to the view that the presence of the glass was due to inadvertence. But what a dangerous inadvertence. Probably the glass was substituted for a harmless sparkling material, having got into the sweets much in the same way that arsenic got into beer. We are aware that sparkling glass is sold wholesale for certain purposes and doubtless this was inadvertently used in the sweets which we examined. The sale of such sweets would imperil the health of the purchaser, but there is no reason for believing that there was fraudulent intention. As we have said, it is possible that a great number of these sweets thus unintentionally (as we think) sprinkled with glass are yet exposed for sale. We have pointed out the danger, and it is for the local authorities to trace it to its source and to stamp it out.

PLAGUE IN CAPE COLONY.

A TELEGRAM received at the Colonial Office on May 23rd gives the following statistics of plague at Cape Town for the week ending May 18th Fresh cases: Europeans, 9; coloured persons, 6; Malays, 2; East Indians, 2; Chinese, 0; natives, 2; total for the week, 21. Corpses found: coloured persons, 3; Malays, 3; East Indians, 1; natives, 1; total, 8. Deaths (including corpses found): Europeans, 2; coloured persons, 9; Malays, 4; East Indians, 1; Chinese, 1; natives, 1; total 17 (*sic*). The total cases and deaths up to May 18th are as follows: Europeans, 164 cases and 52 deaths; other nationalities (Asiatics and African natives), 475 cases and 240 deaths. Total up to May 18th 639 cases and 292 deaths. A private in the Field Artillery, Gibraltar lines, Green Point, has developed plague, bringing up to 46 the total cases among persons under naval and military control. A private in the Army Ordnance Corps died from plague at Port Elizabeth on May 20th. A European in charge of a coffee-stall at Green Point camp has developed plague. Two privates in the 1st Battalion Loyal North Lancashire Regiment at Mafeking have now been officially pronounced to have plague; these men with 20 others arrived at Mafeking from Cape Town on April 19th. The area of infection remains unaltered.

MIND-WANDERING.

IN his presidential address to the Neurological Society Dr. W. Julius Mickle[1] dealt with the subject of mental wandering—a condition which he defined as allied to certain dream-states and delirious or sub-delirious processes. This condition lent itself to both subjective and objective study and observation, and its study threw light on certain nervous and mental states occurring in the borderland between the normal and the abnormal. The patient selected for special study in the present instance was a medical man who, as the result of typhoid fever, developed an abnormal mental condition. The first slight deviation from health occurred on the fifteenth night after exposure to infection, sleep being light and disturbed. The next morning a light "swimming" sensation was felt in the head. In spite of this he continued with his usual work with the result that his malaise and weakness increased, he looked grey and tallowy, had a febrile temperature, and had to take to bed. On the fifth day there were high temperature, headache, mental confusion, and incipient delirium. In comparison with the fever the degree of toxæmia, as measured by prostration, perspiration, insomnia, and delirium, was disproportionately severe. In the confusion and swirl of ideas which characterised this stage the mind was like the "dove from the ark unable to find a resting-place," and seemed in danger of sinking in the "trackless waste of delirium." The wavering Ego was even now partially and fluctuatingly confusing the self with others and with the surroundings. "In confusion and seething turmoil," says Dr. Mickle, "the Ego-group inclined to break up into constituent parts, to confound some of these with, or attach them to, other persons, or to group the constituents afresh." This partial dissociation of the Ego is the result of the action of morbid processes on the "association-centres" of the brain and may be brought about by toxæmia, fever, inanition, and cerebral exhaustion by insomnia or over-exertion. The patient would at times confuse himself with his interlocutor, or he would feel as if he was partially changed into another —or into several others—a condition analogous to certain dream-states—and occasionally the original self would be re integrated and would recall itself with some degree of lucidity. "At one time the delirant seemed to be mainly substituted by three persons of different ages, all suffering like him from typhoid fever." At this point of time the patient had refused to take beef-tea on purely medical grounds which he expressed and of which he could afterwards retain some recollection. When, however, he was expostulated with by his nurse and the reason of his refusal demanded his final reply, after some colloquy, would be, "I'm sure it is not good for them"—for *them*, be it noted. So that he was now, for the time being, assisting in the treatment of his changed and alienated self. During another stage of the illness there appeared a change of the self of another sort, a reduction towards the mental status and disposition of childhood. Dr. Mickle proceeds to point out the delicate complexity and heterogeneity of the Ego. Even in health we discover on careful scrutiny and analysis that manifold and multitudinous elements constitute the Ego, and many of these are loosely united, transient, and readily replaced by others. A process of decay and of renewal, of loss and of acquisition, is continually going on. In the present case certain sensory troubles also supervened, such as paræsthesia of the mouth and teeth, a feeling of general "pulpiness" of the body, and perverted sensibilities of sight. Illusions of sight—e g., landscapes and shipping, panoramic views of plants, paths, and cows—also appeared and vanished in association with some degree of vertiginous feeling. Dr. Mickle seeks to correlate some of these phenomena with rhythmic vaso-motor disturbances in the brain. Temporary bronchitis and treatment of it with inhalations formed the starting point of delusions as to being alternately anæsthetised and suffocated and to vigorous expostulation and denunciation by the patient. He also had phantasmagorial illusions of riding in a coach while actually seated in a chair, of watching a gigantic stringed instrument which he thought was allegorical of human lives, and at one moment even imagined he was a general paralytic. He slowly improved and in the course of about five months was on the high road to recovery.

---

A NEW EXPONENT OF "EDDYISM."

THE Earl of Dunmore has contributed three articles to a daily newspaper, in order that "Christian Science," of which he is apparently an enthusiastic devotee, may be brought home to the multitudinous readers of the halfpenny press. His lordship's summary of the religious doctrines of Mrs. Eddy has little concern for medical readers, save to reveal what they know already—viz , the incomparable credulity of that lady's followers. We learn that she was once a "gentle, pious, unassuming Christian woman," and that now she stands out "far in advance of the common frontage of human mentality"—a very gratifying position for an unassuming woman to occupy; and we are also informed that "(1) there is one Mind (God) and that Mind governs all; (2) that man being God's spiritual Idea is the reflection of this Divine Father." The unravelling and discussing of cryptic phrases such as these we must leave to others, especially recommending the matter to the attention of that large public which enters into journalistic competition of acrostic-guessing. But when we come to an assertion the meaning of which is conveyed by the phraseology we feel bold to make a remark or two. "It was authoritatively stated," says Lord Dunmore, "at the World's Congress of Religions, as long ago as 1894, that more than 1,000,000 cases of disease had been healed by Christian Science up to that date, and that many of these cases had been previously pronounced incurable by the doctors." We should like to know who, in Lord Dunmore's opinion, could be in a position to make such a statement "authoritatively"; and we should like to meet a few of "the doctors" who had given up as incurable the cases which quacks claim to have cured. The public ought to hear what actually was the nature of the alleged disease and the evidence of medical men as to the genuine cure of the condition by Christian Scientists. In particular, we ought to have the names of these "doctors." Unassuming Mrs. Eddy's name is blazoned forth in print, why should not the names of the medical men be also published? Beyond assertions of the kind quoted we have no doubt that Lord Dunmore has given a compendious summary of Mrs. Eddy's teaching, but it is our regret that when we begin to understand what he is driving at we commence at the same time to see that, judged by ordinary canons of reason and experience, this distinguished traveller and excellent nobleman is talking sheer nonsense. Perhaps we ought not to judge by ordinary canons such a sentence as this, which, we believe, sums up the Eddy position with relation to disease: "Metaphysical treatment through the power of Divine Truth is able to heal mortal mind of the illusion of sickness; and when the mind is relieved of its illusion there is no sickness left to disappear." Our "mortal mind" only enables us faintly to picture a cholera microbe or a bacillus of tuberculous tendencies taking a defensive and wholly unsympathetic attitude under metaphysical treatment and refusing to disappear from possibly congenial surroundings. We might even anticipate that the illusion of death might follow the illusion of sickness with unusual frequency among Lord Dunmore's friends, had we full confidence in the zeal of the convert when confronted with martyrdom, and had we not some faith in the sense of Englishmen and Englishwomen prevailing in the long run. When the Christian Scientist is seriously ill, the Christian Scientist's relatives, whether of the cult themselves or not, feel themselves loaded with a somewhat serious responsibility. This responsibility they usually proceed to transfer to a medical man, though possibly not until delay has considerably increased the difficulties of treatment.

INFANT MORTALITY AND THE OCCUPATION OF MARRIED WOMEN.

IT is frequently asserted that the high death rate of infants in large towns is in great part due to general neglect and also to want of breast milk in consequence of the mothers having employment as factory workers and therefore being away from home all day. In a recently published pamphlet,[1] however, Mrs. Florence J. Greenwood, sanitary inspector, Sheffield, shows that a good deal may be said on the other side and that the connexion between infantile mortality and the employment of married women as factory workers is by no means so immediate as has been often assumed. For instance, it is generally agreed that the employment of married women in factory towns is either diminishing or, at least, not increasing, but the infantile death-rate, nevertheless, tends decidedly to rise. The Registrar-General's report for 1899 shows that in 27 out of the 33 great towns it has increased during the past 10 years, and in six towns where it has decreased the reduction is not great, whilst in Burnley, a typical manufacturing town, during 1899 there were 269 deaths under one year of age per 1000 births, or an excess of 61 per 1000 over the average of the preceding 10 years. Again, a similar inference is to be drawn from the statistics of Chesterfield, a town of about 25,000 people, situated in the centre of a mining district in

---

[1] John Bale, Sons, and Danielsson, 83-89, Great Titchfield-street, W.

Derbyshire, where there is little or no employment for married women. In 1898 the infantile death-rate for England and Wales was 161 per 1000 births; in Sheffield, with a population of over 360,000 and a small population of married women employed as trade workers, it was 195 per 1000; in Chesterfield, a country town, it was 228 per 1000. Mrs. Greenwood supports the view that these high infant mortalities are due principally to improper feeding, insufficient clothing, and general domestic mismanagement. She believes that more good can be done by house-to-house visitation and advising parents than by any legislation tending to prevent women from working in factories.

ABDOMINAL PAIN IN TYPHOID FEVER.

THOUGH abdominal tenderness is one of the recognised symptoms of typhoid fever the question of spontaneous abdominal pain apart from complications is little considered in the text books The introduction of the operative treatment of perforation has rendered this question important, for pain is the most constant symptom of perforation. Professor Osler, in a valuable paper on the study of the symptoms of perforation with view to early operation,[1] points out that severe abdominal pain in typhoid fever may be associated with pleurisy, cholecystitis, a distended bladder, or a loaded rectum, or may follow the administration of an enema. In the *New York Medical Journal* of May 4th Mr. Thomas McCrae, assistant resident physician of the Johns Hopkins Hospital, has published an important paper on abdominal pain in typhoid fever based on observations made in Professor Osler's clinic. Typhoid fever is becoming more and more a disease which is treated in hospitals. The recognition and estimation of serious abdominal symptoms must often depend on the resident medical officer. The question of the cause of pain may confront him suddenly and other symptoms may be contradictory or deceptive The diagnosis of perforation may be most difficult, but decision is imperative for early operation is all-important Mr. McCrae has made a careful study of the symptom of abdominal pain in a series of 500 cases of typhoid fever. In 206, or 41 per cent., there was neither pain nor tenderness; in 72, or 14 per cent, there was tenderness without pain; and in 222, or 61 per cent., pain was present at some period. Out of these last cases pain was present only at the onset in 61, which leaves 161, or 32 per cent. in which pain was present during the course of the disease In the first group (in which there was no pain or tenderness) it is of interest that conditions which sometimes cause pain—tympanites, diarrhœa, and hæmorrhage—were found. These cases were mild as a rule; eight were fatal. Pain present at the onset of typhoid fever may lead to erroneous diagnosis: in cases associated with diarrhœa in which high fever is absent enteritis may be diagnosed; if the abdominal symptoms are more severe and there are localised tenderness, rigidity, &c., appendicitis or peritonitis may be diagnosed. In four cases this error was made. Abdominal pain during the course of the disease may be due to: 1. Conditions apart from any special lesions of the disease—hysteria, pleurisy, pneumonia, distended bladder, labour, and menstruation In the series pain was due to hysteria in four cases, to pleurisy in two, to pneumonia in one, to distended bladder in four, and to menstruation in one. 2 The pain may be due to disturbances of the gastro-intestinal tract apart from complications. In two cases the pain was due to the taking of solid food which was smuggled into the hospital by friends, in three it was associated with severe and protracted vomiting, in 10 it was apparently due to constipation (fæcal impaction in three), in two it was associated with the administration of an enema, and in 16 it was associated with diarrhœa. 3. The pain may be due to abdominal conditions apart from the specific intestinal lesions. In two cases it was due to appendicitis (apparently not typhoid). In one case it was due to peritonitis; the patient had recently undergone operation for pyosalpinx. In three intestinal obstruction—after operation for perforation in two and for hepatic abscess in one—was the cause. In four cholecystitis and in one hepatic abscess was the cause. In 10 the pain was associated with a tender spleen. In four phlebitis of the iliac vein was the cause of severe abdominal pain. 4. The pain was associated with hæmorrhage in 14 out of a total of 36 cases of this complication In some cases it came on in paroxysms, in others it was more continuous. 5 Pain from perforation occurred in 13 cases; in all it was severe. These cases may be divided into two groups—those with sudden onset, of which there were 10, and those in which pain preceded the perforation for some days. In four the pain was accompanied by vomiting. In three the pain at the onset was referred to the penis. This sudden onset of pain is very suggestive of perforation. The nurses should be instructed to send immediately for the medical officer when it occurs. It is important to see the patient at once, for the severity of the pain may pass off in a few minutes and the patient be comparatively comfortable. The most careful examination should be made, noting every symptom as advised by Professor Osler.[2] An endeavour should be made to exclude all other possible causes of pain. The pain did not remain constantly severe in any instance but was paroxysmal, the patient in the intervals being almost free from pain Should the patient be then seen—for example, by a consultant—a very different picture may be presented to that found a short time previously In such cases, perhaps, a couple of hours should be spent in frequent observation of the case. Only thus may it be possible to estimate the character of the pain. In one case recurring paroxysms of severe pain with increased respiratory rate were the only symptoms of perforation during eight hours; then tenderness and rigidity suddenly supervened. Next to cases of perforation in which there is no pain those in which there was no sudden onset and possibly no increase of the pain previously present are the most difficult to recognise There were three such cases in which pain was present for five, nine, and 10 days before operation respectively. In one a sudden severe exacerbation suggested perforation, in the second vomiting suggested the general peritonitis which was found on operation, and in the third the perforation was not recognised. 6 Pain without discoverable cause was present in 70 cases—a surprisingly large number. It was usually not severe and was of short duration. The majority of these cases showed no special features, but one group was important because perforation was simulated; leucocytosis and abdominal symptoms—tenderness, rigidity, &c.—were present. Possibly some undiscovered inflammatory complication was the cause of these symptoms. Leucocytosis in typhoid perforation has recently been discussed in an annotation which may be read in connexion with the present one[3]

HONOURS TO EDOARDO PORRO.

AN Italian contributor, under date Milan, May 24th, writes:—"The Senator, Dr. Edoardo Porro, professor of gynæcology in the Regia Scuola Ostetricia of Milan, has just received gratifying testimony of the admiration and affection entertained towards him by his colleagues and fellow-workers in his own branch of the profession. Twenty-five years have elapsed since he devised and performed the operation to which he had given his name, but his clinical and consultant activity during the interval has been scarcely less salutary to the lay world and honourable to the medical cause. Interpreting a sentiment not confined to his native Lombardy but universal throughout the Italian kingdom, a strong committee, of which his colleagues Dr. Mangiagalli and Dr. Decio were the leaders, raised funds by subscription for a massive gold medal to be struck in his honour, the artistic elaboration of which was entrusted to the well-known masters in that *métier*, Signor Cappuccio, Signor Boninsegna, and Signor Johnson of Milan. The result is in all respects worthy of Edoardo Porro. On the obverse a three-quarters profile in strong relief renders vividly and happily the characteristic North-Italian head, with the masculine yet refined features aglow with intelligence, decision, urbanity, and benevolence. Encircling the head, in capital letters, are his name and place of origin: EDVARDUS PORRUS MEDIOLANSIS. On the reverse, reposing on a floral wreath, up which the Serpent of Epidaurus has worked its way, rests an oblong tablet inscribed as follows: SECTIO CAESAREA . SALUBRIOR INSTITUTA . AN . MDCCCLXXVI . COLLEGÆ ET AUDITORES AN . MDCCCCI. On the same day the illustrious gynæcologist was presented with another testimonial, equally significant, an address inscribed on a 'targa artistica' (artistic shield) and signed by office bearers of the Società Italiana delle Levatrici (Society of Italian Midwives), of which he is president. No one was less prepared for this touching demonstration than Professor Porro himself, and the scene was one never to be forgotten by those who waited on him at his residence, when amid words of reciprocal affection and gratitude the testimonials, as a κτῆμα εἰς ἀεί, passed to their worthy destination."

UNCERTIFIED DEATHS IN THE HEBRIDES.

WHEN the time comes round for procuring any adequate attention to the treatment of the sick poor in remote districts, the claim of such persons in the Hebrides for early consideration will be very strong. The tenth annual report of Dr. Ogilvie Grant, medical officer of health of the county of Inverness, is one of great interest. It gives much information of the difficulties in the way of a health officer who has to make journeys to the remote islands in the west, more difficult to accomplish and requiring more time than journeys to Paris or Berlin. It contains tables for the past 10 years of deaths and death-rates, of longevity, of density of population, of infantile mortality, of causes of death, of uncertified deaths, of births and birth-rates, of old age, of meteorology, and of notified diseases. Dr. Grant dwells with much satisfaction on the increased efforts to grapple in all its forms with tuberculosis which has been a deadly disease in these districts in Scotland. But he dwells with very opposite feelings and with much reiteration on the fact that in the country an enormous number of persons still die without any medical assistance. In the last year under the head of "uncertified' deaths" he says that it is deplorable that in the county of Inverness nearly 400 persons died and were buried without any knowledge about, or investigation of, the cause of death, as far as the medical profession was concerned. Thus, of 80 deaths registered in the parish of Duirinish 51 were uncertified, of 47 deaths in Kilmuir 33 were uncertified. In the parish of Portree, of 55 deaths registered 27 were uncertified. In the parish of Sleat, of 27 deaths registered only four were certified. In Harris, of 111 deaths registered 57 were uncertified. In North Uist, of 85 deaths registered 26 were uncertified, and in South Uist of 85 deaths registered 57 were uncertified. Taking a period of 10 years into view in the Island of Skye alone there were no less than 1426 uncertified deaths, and in South Uist district there were 770 During the same period in 10 years in this single county "nearly 4000 persons have gone to their graves unalleviated by medical care." We shall not moralise on so pitiful a fact but commend it to the Local Government Board for Scotland The medical profession cannot be blamed for it. Nor can the medical journals. The General Medical Council, too, has urged the matter in various ways on the attention of the Government. Even the war does not excuse the Government for such indifference as is displayed in allowing the continuance of such a scandal as 4000 deaths in one county in 10 years with no provision for medical attendance. In many of these cases, doubtless, life itself would have been saved by proper medical supervision and in most of them unspeakable suffering would have been averted or reduced to a minimum. A remarkable instance of an isolated population deprived of medical aid is reported from the three islands of Arran, situated off the west coast of Ireland, 30 miles from Galway. Communication with the mainland is limited to a steamer from Galway three times a week, if the weather permits, and an occasional small sailing vessel. Typhus fever is of not infrequent occurrence in the island and Mr. T. Kean, the dispensary medical officer, fell a victim. During his illness, which unfortunately proved fatal, he is said to have been without medical attendance for a week and the Galway Board of Guardians, as the local authority, is much blamed for permitting this deplorable state of matters.

THE PATHOLOGICAL SOCIETY OF LONDON

THE council of the Pathological Society of London having proposed certain alterations in the mode of conducting the business of the society, these proposals were submitted to the annual meeting held on May 21st and were adopted. The work of the society will now be carried on in four sections, and certain vice-presidents have been elected to act as chairmen in these sections, and secretaries have likewise been elected who will each arrange the proceedings of his own section, and members of the council have also been deputed to act as committees of the several sections. Section A will be concerned with Pathological Anatomy and Histology: its chairman will be Dr. J. F. Payne, and the secretary will be Dr. H. Morley Fletcher; the committee will consist of Dr. J. Galloway, Dr. C. D. Green, Dr. H. D. Rolleston, Dr. N. Dalton, Dr. G. F. Still, Mr. T. W. P. Lawrence, and Mr. D'Arcy Power. Section B will deal with Bacteriology. the chairman will be Dr. E Klein, F R S, and the secretary Mr. A. G. R. Foulerton; whilst the committee will include Dr. F. W. Andrewes, Dr. W. Bulloch, Dr. Allan Macfadyen, Professor John McFadyean Mr. H. G. Plimmer, and Mr. W. C C. Pakes Section C will study Experimental Pathology: the chairman will be Dr. F. W. Pavy, F.R.S, and the secretary Dr T Grigor Brodie; whilst the committee will be formed by Dr W. S. Lazarus-Barlow, Mr. Walter Edmunds, Professor E. H. Starling, F.R.S., and Mr. C. A. Ballance. Finally, Section D will be concerned with Chemical Pathology. the chairman will be Professor W. D. Halliburton and the secretary Dr. A. E. Garrod; and the committee will consist of Mr. F. G. Hopkins, Dr. Vaughan Harley, and Dr. S. G. Hédin. It will be interesting to see how this new scheme will work. We believe it will be found greatly to increase the value of the society and to accentuate the advance of pathological knowledge. The large number of physicians and surgeons who have done special work in the various branches of pathology as above indicated, and who have been appointed in some capacity to the different sections, will doubtless take an increased interest in the work of the society generally, and a friendly rivalry will probably exist between the sections to forward as far as possible original research and to encourage those who have special opportunities of studying and observing morbid specimens and pathological processes to bring the result of their observations before one or other of the sections, so that the members who frequent that section will be able to criticise and to suggest much to the advantage of pathological work in general.

CHELSEA CLINICAL SOCIETY.

THE fourth annual dinner of the Chelsea Clinical Society was held at the Criterion Restaurant, Piccadilly-circus, W., on May 23rd. There was a large attendance of members and guests under the chairmanship of Dr. William Ewart, the retiring president of the society. After the health of "The King" had been duly honoured Dr. Ewart proposed the toast of "The Chelsea Clinical Society" and dwelt upon the great advantages likely to accrue to that society from its association with the Jenner Institute of Preventive Medicine. The latter institution has generously offered to the society the use of its rooms for meeting purposes and the meetings of the society next session will probably be held at the Jenner Institute Kindred societies were replied for by Dr. Archibald Garrod and Dr. Dundas Grant and the visitors by the Rev. H. J. Kitcat. Mr. C. A Morris, the president-elect of the society, Mr. Foster Palmer, and other members spoke during the evening, the speeches being pleasantly interspersed with music.

BLUE URINE.

THE case recorded in another column of a patient who passed blue urine is a good illustration of a rare phenomenon, and Mr. John Good deserves thanks for having brought it to the notice of the profession. Methylene blue is now fairly frequently prescribed in neuralgia and kindred affections. The urine of patients taking this drug becomes coloured blue, but this cause of the colour of the urine cannot apply to Mr. Good's case; he made careful inquiries and satisfied himself that his patient had not been taking methylene blue. We believe the etiology suggested by Mr. Good to be the correct one—namely, that indol was produced from the products of proteid decomposition. Indol by the putrefactive action of the bacillus coli forms indican, which on oxidation causes the formation of indigo. For these chemical changes to occur before the urine is passed is most rare, but this phenomenon has been noted in cholera and in typhus fever. The blue colour is more frequently seen when the urine has been exposed to the air and is becoming decomposed. Indican occurs in the urine more particularly in cases of constipation and in cases of long-continued intestinal obstruction. Professor J. Rose Bradford, writing in Professor T Clifford Allbutt's "System of Medicine," states that it is also found in cases of putrid inflammation, such as putrid empyema and gangrenous pneumonia, also in tuberculous peritonitis, gastric ulcer, cancer, and other diseases. Should the indican become oxidised in sufficient quantity, the urine may then become blue from the formation of indigo. The latter substance is occasionally found in urinary sediments and calculi.

IN connexion with the establishment by the Metropolitan Asylums Board at Rochester House, Little Ealing, of a training-school for 150 imbecile children of a more hopeful type than the mass of those congregated at Darenth, Dr. G E. Shuttleworth (now examiner of defective children to the London School Board and formerly medical superintendent of the Royal Albert Asylum, Lancaster) has been appointed medical expert, and Dr. R. Halstead Dixon visiting medical attendant.

THE *London Gazette* of May 28th officially announces the following appointments to the Royal Victorian Order:—To be a Knight Commander: Mr. Frederick Treves, C.B. To be a Commander: Mr. Alfred Downing Fripp, C.B., M V.O. To be a Member of the Fourth Class: Dr. William Augustine Ellison.

MR. JAMES GRAHAM, M.A., M.D. Edin., M.B. Sydney, the Mayor of Sydney, whose knighthood was recently announced, was knighted by the Duke of Cornwall and York on May 29th at a *levée* held at Government House, Sydney.

THE Jubilee Festival (1850-1901) Dinner of the Islington Medical Society will be held at the Café Royal, Regent-street, London, W , on Wednesday, June 5th. The chair will be taken by Dr James Grey Glover, J.P.

MR J. BLAND-SUTTON will be a candidate for a seat on the Council of the Royal College of Surgeons of England at the next election.

THE REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR 1899.

CONCLUDING NOTICE.[1]

THIS question of the vastly increased susceptibility of the European soldier to be attacked by typhoid fever during the first two years of his service in India, and notably during the first year, has been so frequently alluded to by us that there is no need to dwell upon it now. The fact has been repeated for so many years in Indian statistics of the disease that it may be taken as established and it has a most important bearing upon our military occupation and rule of India. The European military population of that country may be said to constitute a great etiological and pathological experiment. The white population of India is almost exclusively made up of individuals of that time of life which may be termed the enteric fever age in all countries, and as far as the army of India is concerned its numerical strength is maintained under a short-service system by being annually replenished with fresh arrivals of young soldiers from the United Kingdom who, during their earlier years of Indian service and whilst they are undergoing a process of seasoning, acclimatisation, or of "survival of the fittest"—call it what we will—form a material highly susceptible to typhoid fever. The comparative freedom of the British garrison at Aden from this disease falls in with the foregoing observations, for the troops garrisoning Aden are usually composed of corps which are on the homeward route after having served their time in India.

One of the most important and interesting points connected with the prevalence of typhoid fever in India is as to whether the native population suffer from that disease. If it could be shown that they did then we need not go far in seeking for an explanation of its spread among Europeans, for with the customs and habits of the natives of India the disease-cause would be widely distributed in the surface soil That cases of the disease do occasionally, though rarely, occur among them is not denied, but what is denied is that the races of India do, as a rule, suffer from the disease. On the contrary, it is contended that they are, practically speaking, immune, and as far as there is any positive evidence on the point of a statistical and clinical character, it is strongly corroborative of this view, as we have frequently had occasion to point out. Assuming its general correctness—as must, we think, be done, if only for the sake of argument, there are several ways in which it has been accounted for. That more especially favoured is that the diarrhœal disease to which native infants and children are subject is in reality typhoid fever. If this be so it is, of course, easy to explain the relative, or nearly absolute, absence of that fever in the adult native population. The native, it may be said, having paid his tribute to typhoid fever in early life acquires thereby a relative immunity from subsequent attack. But in the case of Europeans at home it is difficult to diagnose typhoid fever from the clinical symptoms alone, and it is confessedly still more difficult in the case of the natives of India, where the term "fever" has a very wide and undefined significance and where it has been the practice to collect together a number of undifferentiated fevers and diseases of an anomalous sort and to affix one and the same label—that of fever—to the lot. On the other hand, typhoid fever does not appear to be a common complaint among the children of European parents resident in India.

---

[1] The first notice appeared in THE LANCET of May 11th, 1901, p. 1352.

An attempt, we are glad to say, is now being made to investigate this subject and to solve the problem of the prevalence or not of typhoid fever among the native populations of India by having recourse to a more exact and scientific method for its diagnosis than can be obtained where we have to depend solely upon a consideration of the symptoms and clinical history. We refer to the diagnosis of typhoid fever by means of the serum agglutination and sedimentation reaction test. An experimental investigation of this nature is now being carried on in connexion with the Research Laboratory at Bombay, and there is an interesting report on the subject in the *Indian Medical Gazette* for April last by Captain George Lamb, I.M.S. This medical officer considers that typhoid fever is much more common amongst natives, especially children, of India than is commonly supposed. This branch of study is, however, still in its infancy, and in the meantime it is quite allowable to indulge in some speculation based on the ascertained facts so far as we know them in regard to the alleged non-prevalence of typhoid fever among the native Indian population. It is a subject, as we have said, to which we have more than once called attention. That cases of this fever do occasionally occur among them is admitted, but their number is quite insignificant in comparison with those which occur among the European population in their midst. It is also a somewhat significant and noteworthy fact that the cases of typhoid fever which arise, for example, among the native army of India are most commonly recorded among Ghoorka troops coming from Nepaul (an elevated district with a relatively cool climate) to the plains of India. These are meat-eaters and spirit-drinkers like the British troops, whilst the natives of India are not. Moreover, we know how the habits of the natives and the disposal of night-soil in and around native jails lend themselves to soil-contamination but without, so far as ascertained facts are to be relied upon, causing the spread and prevalence of typhoid fever. May it not be that the great liability of the European in India and the immunity of the native to this form of fever is not so much attributable to any racial differences as to differences of food—that diet may be reckoned among the factors productive of enteric fever—that the typhoid bacillus, for example, may find a favourable soil, especially adapted to its growth and development in a flesh-feeding people which it does not find in the graminivorous races of India? It may be that there is a great difference between the two in regard to the nature and composition of their fæcal products, or in the bacterial intestinal flora in the two cases. Supposing this to be so, it would be easy (if we take note also of the factors of youth and recent arrival in the case of the European soldier) to account for the great liability of the British to be attacked and to die from this fever as compared with the native soldier on the one hand and the innocuous non-infectious properties and nature of the fæcal discharges of the latter on the other—the bacillus of Eberth or the disease-cause, be it what it may, not being present in such discharges owing to their not affording a suitable nidus for it. On physiological grounds it would seem that the nature of the food consumed by the natives of India is better adapted to the climate than is a dietary in which meat and beer (alcohol) enter so largely. It would however, be both impracticable and unwise, as far as the European soldier is concerned, to make any great change in this respect, but it might be possible, nevertheless, to consider whether his diet could not be more assimilated to that of the native and the requirements of the climate than is the case at present.

The typhoid bacillus must be much more widely distributed in nature than is generally imagined, and it is no longer tenable that enteric fever is an exclusively water-borne disease. The trend of scientific opinion in the present day is in the direction of the soil, although no essential difference has been made out between the soils of fever and non-fever areas—at least, that seems to be the reading of some of the latest researches and of the valuable pioneer work carried on by Dr. Sidney Martin and Dr. A. C. Houston of the Research Department of the Local Government Board in the recently published report for 1899–1900.

The truth is that there is still a great deal to be learned about the etiology and spread of typhoid fever and that much of the teaching and doctrine in regard to the subject has been hitherto expressed in a too peremptory and dogmatic way. Without assuming, for instance, that the bacillus coli becomes changed into the enteric bacillus we do not yet know all about the relations of one to the other and there exists a good deal of evidence to show that Sanarelli's experimental results are applicable to typhoid fever in the human subject and that auto-intoxication with the products of intestinal fermentation is a factor in the causation of typhoid fever. We now find that the typhoid bacillus will grow readily in some kinds of soil which have been sterilised and that, on the other hand, it would almost look as if the putrefactive bacteria were among its more formidable antagonists, and in the Sanitary Commissioner's report under review Professor Hankin is quoted to the effect that the enteric fever microbe is one that flourishes better in comparatively pure than in very polluted water.

We have devoted a large amount of space to this subject of typhoid fever in India at the risk, we fear, of wearying our readers, but the subject is one of great importance, considering the drain which this fever annually makes on the health and life of the young manhood of this country. We would only add one further remark and it is this: How far would it be practicable to introduce the biological system of drainage into Indian stations and military cantonments in place of the existing dry-earth system which, despite its advantages and simplicity, is nevertheless attended with difficulties and many possible risks and dangers to health? Passing on to other subjects in the report under notice, we find that there were altogether 83 cases of scarlet fever and six deaths in the European army in India—a disease of rare occurrence there. If we recollect aright the occasion of the importation of the infection to India was first of all recorded some years ago by Surgeon-General T. Maunsell, C.B., and the fact was noticed in Watson's "Practice of Physic." The infection on the present occasion (1899) was imported in the transport *Simla* and all, or nearly all, the cases were traceable to that source.

At pages 56 and 57 of the report there are some interesting data about dysentery and hepatic abscess. It may be mentioned that the mortality from the latter disease was 32 times greater among the European troops than among the native troops, while the admission-rate for dysentery was higher among the native soldiers. We pass over the statistics and remarks on venereal diseases, which show a decreased prevalence (pages 58 and 59), because we do not think that there has yet been time to form any correct estimate of the effect of the new measures which have been, or are being, adopted.

At pages 61 and 62 there are some brief remarks on the vital statistics of officers, women, and children which are worth being referred to if only because they so often escape notice owing to the space devoted to other subjects. A note is added illustrative of the need for caution in the use of serum diagnosis (Widal test).

Our review has already extended to such a length that we must omit all allusion to the sections devoted to the native army, the jails of India, and the general population. Section X. of the report (page 231 *et seq.*), under the head of "General Remarks," discusses in an interesting sketch the scientific work which has been undertaken in the investigation of Indian fevers and the progress of preventive inoculation for enteric fever.

NOTIFICATION OF TUBERCULOSIS.—Dr. W. H. Symons, the medical officer of health of Bath, in his annual report for 1900 mentions that 82 deaths occurred from tuberculosis. After every death from tuberculosis a visit is paid to the house, inquiries are made, free disinfection is offered, and advice is given as to the prevention of the disease. Dr. Symons adds that the voluntary notification of tuberculosis, with the consent of the patient, came into force on Nov. 24th last.

MEDICAL MEN AND THE WORKMEN'S COMPENSATION ACTS.

III.[1]

ALLUSION has been made in preceding articles to the medical referees constituted under the Workmen's Compensation Act of 1897 and to some of their duties The medical referee has now been in existence for some years, and medical men have had experience of the responsibilities and difficulties of the post The position assigned to him by the legislature is one of considerable importance, but the questions upon which he is intended to be the final arbiter are frequently questions upon which no human being could truthfully give the conclusive answer which the legislature seems to expect For example, the employer wishes to put an end to weekly payments made to an injured workman who, he alleges, has completely recovered The workman claims to be still suffering from symptoms which, he says, are the result of the accident The question of whether he so suffers and whether the symptoms are due to the accident, or not in any way connected with it, may provoke conflicting opinions honestly formed by two competent medical men who have seen him from time to time ever since the accident took place, and perhaps before it. On their differing in opinion the matter is referred to the medical referee, perhaps a year or two after the accident, in order that he may read the medical evidence, examine the patient, and report It is quite possible that his report in such circumstances may wisely leave the continuance of the workman's compensation largely to the discretion of the judge or arbitrator.

The duties of the medical referee (apart from those which we have mentioned in the second article, where a workman, dissatisfied with a medical examination made on him during the continuance of his weekly payments, goes on his own account to the medical referee) are performed on the appointment or at the request of the county court judge or arbitrator in accordance with the schedules of the Act of 1897 and sundry rules and regulations duly made in accordance with that Act The principal provisions of these are as follow —

> Schedule II., Sec 13.—The Secretary of State may appoint legally-qualified medical practitioners for the purpose of this Act, and any committee, arbitrator, or judge may, subject to [illegible] the Secretary of State and [illegible] to report on any matter [illegible] in the arbitration, and th[illegible] shall, subject to Treasury [illegible] vided by Parliament.

Regulations, dated May 2nd, 1898, made by the Secretary of State and the Treasury :—

> *Regulation 2*—Before making any reference the committee, arbitrator, or judge shall be satisfied, after hearing all medical evidence tendered by either side, that such evidence is either conflicting or insufficient on some matter which seems material.
>
> *Regulation 3*—Every reference shall be made in writing [illegible]

Simultaneously with the making of the reference as above the injured man is ordered to submit himself for examination by the medical referee, or if he is not in a fit condition to travel this is to be stated in the reference The reference has to be duly signed by whoever makes it, and countersigned by the registrar of the county court, who shall insert in it the name of the referee proper to be appointed, if no such name appear on it, and shall forward it to the medical referee, and the medical referee shall not [illegible] unless it is duly signed and sealed [illegible] "reference" the medical referee appoint[illegible] for the examination of the injured m[illegible] sends him notice accordingly, examines him and the evidence submitted, gives his report in writing, and forwards it to the registrar from whom he received the reference

> *Regulation 18*—The committee, arbitrator, or judge may, by request signed and forwarded in the same manner as the reference, remit the report to the medical referee for further statement on any matter to be specified in such request.

The medical referee, therefore, is an expert adviser or assessor of the judge or arbitrator, and is not in any circumstances a witness, although he may be summoned to be present at the hearing of a case in which he has reported. The legislature imposes considerable responsibility upon him, but in return it shows confidence in his skill and a laudable desire that the evidence of medical witnesses which may with perfect fairness be conflicting or which may almost unavoidably be coloured by circumstances shall be weighed by one who is himself an expert and who by his position should be absolutely impartial.

The regulation governing the presence of the medical referee during the arbitration is as follows :—

> [illegible] being called as a witness

With regard to the fees to be asked by the medical practitioner not a referee in cases where he is required to make an examination under the Act no scale is laid down, but medical men must settle a reasonable fee in accordance with their knowledge of the circumstances of those who will pay it, whether individuals [illegible] The following are the fees fixed [illegible] compensation of the medical refere[illegible] the Treasury, the medical referee [illegible] Office each quarter in a prescribed form a statement of the payments due to him

> 1 For a first reference, to include examination of the injured workman and written report, two guineas.
>
> 2. For a further statement under Regulation 18 on any matter not covered by the original reference, one guinea
>
> 3 For a second or subsequent reference to the same referee in a further arbitration on the same case, to include examination, if necessary, and written report, one guinea
>
> 4 Where a medical referee attends at the request of the county court judge or appointed arbitrator, for such attendance three guineas.
>
> 5 Where, in order to examine the injured workman or to attend on [illegible]

The above may afford some idea of the views of the Treasury as to reasonable fees in cases of the kind contemplated.

In writing of the Workmen's Compensation Acts we have only dealt in general terms with those portions of them which are likely to be of interest to members of the medical profession at large who may at any time, particularly now that the "workman in agriculture" is a subject of compensation, be called upon to observe them. We do not quote the whole of the rules and regulations dealing with medical referees because we are inclined to assume that those who from time to time are appointed as such will possess themselves of copies of the Acts, regulations, and forms under which they have to perform their duties, or will purchase some legal handbook containing them, together with notes upon them. There are many such, some of them stocked with a considerable amount of learning, on the vexed questions decided or likely to arise in construing the Act, those by Messrs Beven, Ruegg, and Minton Senhouse being, perhaps, the principal ones. A handy small book not over burdened with matter of this kind, which to a medical man is superfluous, is entitled "The Workmen's Compensation Act," by W. A. Willis, barrister-at law It costs 3*s* 6*d*. and is published by Butterworth and Co, Fleet street, and Shaw and Sons, Fetter lane As far as we know a new edition has not been brought out since the Act of 1900 but pre[illegible] [illegible] Acts will insure, and for the benefit of medical men who may have "workmen in agriculture" in their employment, and who do not wish to be responsible for all the accidents which may happen to them, we mention that they can be insured at the moderate premium of 3*s* for every hundred pounds paid in wages, the rates for other workmen varying from 5*s* to £1 5*s* per hundred pounds paid in wages, according to the nature of the dangers associated with the insured persons' work.

---

[1] Parts I. and II. appeared in THE LANCET of May 18th (p. 1370) and 25th (p. 1457) respectively

THE MEDICAL, SURGICAL, AND HYGIENIC EXHIBITION.

THIS annual exhibition maintains its popularity, as is evident from the increasing attendance year by year. Last year there were present, according to the statement of the chairman of the Organising Committee, Mr. Fred Weiss, in his inaugural speech on the opening day (May 28th), over 3000 medical men. The committee, he added, were very much encouraged this year by the number of applications made by new exhibitors.

On Tuesday afternoon the Queen's Hall, Langham-place, W., presented an animated appearance, calling to mind an Oriental bazaar rich in colour and abounding in air redolent with an indescribable mixture of aromas. One very interesting and important feature of the exhibition this year was the display of sanitary appliances for special medical and surgical purposes and for everyday purposes also. Considerable progress has been and is being made with appliances of this class, such as lavatory basins, water-closets, operating room sinks and tables, hospital sinks, &c., the aim being to secure greater cleanliness and convenience in operation than was hitherto possible. We shall describe some of these appliances at a later stage in this article. Of course there must be a certain amount of the commercial element connected with this exhibition, but we were glad to find that, on the whole, the visitors were spared much of the annoyance of the appeal of the tout which is too often characteristic of this kind of "exposition." Each section, as implied in the title of the exhibition, was well represented, drugs, special foods, surgical appliances, sanitary appliances, miscellaneous articles, periodical literature, books, &c., forming an attractive and engaging *tout ensemble.*

Fine chemicals, alkaloids, and drugs constituted the excellent collection of specimens shown by Mr. E. Merck (Darmstadt) whose London office is at 16, Jewry-street, E.C. As is well known, Mr. Merck issues periodically his "Notes on New Remedies" which give full information on the recent additions to pharmacy. Amongst the specimens shown were jequiritol and jequiritol serum (a substance which produces artificial conjunctivitis), bromipin and iodipin in capsules, the new halogen oils, various glycerophosphates, cacodylates, physiologically pure sodium salicylate, hæmol, hæmoglobin in scales, and other fine preparations. Besides "hypodermules" of suprarenal gland solution with and without chloretone, Mr. Frank A. Rogers (327, Oxford-street, London, W.) exhibited a series of special sprays for treatment of the larynx and naso-pharynx. The method of spraying into the nose or throat direct from hypodermules or sterilised sealed glass capsules is worth attention. Messrs. Cooper's exhibit (80, Gloucester-road, London, S.W.), though tastefully decorated with syphons of the oxy-carbonated water now connected with their name, showed also a series of fine drugs as well as different forms in which they may be administered. Amongst the former may be mentioned acoin (a local anæsthetic and for ophthalmic injection), various cacodylates, nirvanin (an anæsthetic giving a longer effect than cocaine), and amongst the latter cachoids (that is, soluble wafer capsules) gelatin capsules, medicated pastilles. The exhibit also included the "globena" meat essences. Besides palatinoids and bi-palatinoids (which afford an ingenious and satisfactory way of administering drugs), Messrs. Oppenheimer, Son, and Co., Limited (179, Queen Victoria-street, London, E.C.), exhibited traumatol or cresylic iodide which is, as we have pointed out, a powerful bactericide not inferior to mercuric chloride while it is, comparatively speaking, non-toxic. The exhibit included a new hypodermic case and some medicine cases suitable for attachment to a bicycle. Messrs. Parke, Davis, and Co. (111, Queen Victoria-street, London, E.C.) represented their specialities in standardised fluid extracts, chocolate-coated tablets, elixirs, soluble elastic capsules, and sera. We have recently described adrenalin which is regarded as the active principle of the suprarenal gland. The exhibit included an interesting series of compounds of mercury, silver, copper, and iron with nucleinic acid. Similarly we have recently called attention to some favourable features of the Abbey Effervescent Salt (144, Queen Victoria-street, London, E C). It is composed of well-known saline aperients and is agreeably effervescing. The interesting preparations known as bromaurum and hydraurum were the feature of Messrs. Arthur and Co.'s stall (69, Berners-street, London). They have been used in a variety of maladies—in rheumatism, epilepsy, hysteria, and diabetes. The neutral solution of lime and iron, the biniodide antiseptic soap, and a special cream soap, cleansing and antiseptic, are also worthy of mention. Messrs. Rebman, Limited (129, Shaftesbury-avenue, London, W.C.), besides exhibiting recent publications, had a space assigned for serum preparations which are sold in cases containing two hermetically sealed flasks each. Amongst these were Lustig's and Haffkine's anti-plague vaccine and Yersin's serum.

There was a great variety of special foods shown, the majority of them being either milk itself modified in some special manner or a milk product. The Aylesbury Dairy Co. (St. Petersburgh-place, Bayswater), for example, showed all sorts of modified milk, peptonised milk, humanised milk, sterilised milk foods, and sparkling Koumiss. The exhibit included a very interesting series of products illustrating the researches carried out in the company's laboratory on the composition of human milk contrasted with the milk of the cow, the goat, the ass, and the mare. The exhibit afforded excellent evidence of the system of scientific control which this company, to their credit, have rigidly adopted. Plasmon is now well known as the soluble proteid of milk unimpaired in any way in the process of preparation. The representatives of the company (56, Duke-street, London, W.) demonstrated some very interesting applications of plasmon, as, for example, in whipped form, in ices, in beef-tea, in cocoa, and so on. An excellent example of the modern scientific way in which the business of a dairy is carried on was well typified in the exhibit of Messrs. Welford and Sons (Elgin-avenue, Maida-vale, London, W.). This company make a very special feature of asses' milk, a herd of milch asses being kept expressly for this purpose under the strictest sanitary precautions. The exhibit included peptonised, humanised, and sterilised milk, all produced under the same control of a large scientific staff. Peptore is the precipitated proteid of milk prepared by the Protene Co., Limited (36, Welbeck-street, London, W.). Protene has many valuable applications, as in bread, biscuits, and in diabetic foods. The advantages of Hovis (Macclesfield and London) bread are well known; it contains the germ of the wheat and possesses an attractive nutty flavour and is never dry. By the use of Hovis flour the germ of wheat may be included in biscuits and other articles of food An interesting addition to the exhibit this year was "Lito," a new self-raising flour. Close by this stall was Cerebos Salt, which is now recognised as a great advance on the old table and culinary article, keeping not only dry and in a fine form, but containing also a small proportion of the soluble phosphates (3, Maiden-lane, London, E C) Amongst nutrient meat preparations must be mentioned as of distinct merit "Hipi," a pure mutton essence (G. Nelson Dale and Co., 14, Dowgate-hill, London, E.C.). As we have shown in our columns it is a really nourishing and palatable article, affording an agreeable change from the more often used beef extract Messrs. Fairchild Brothers and Foster (Snow-hill-buildings, London, E.C.) showed their well-known digestive and digested products. Amongst the former is pepsencia (a solution of the essential organic ingredients of the gastric juice taken directly from the peptic glands), pepsin in tablets now known as "pepules," and enzymol, a solution obtained from the stomach glands in a carefully sterilised menstruum. An interesting application of this latter enzyme is in dissolving albuminous matter in the various forms occurring in false fibrinous membrane, sloughing tissues, &c. Of digestive products panopepton may be mentioned perhaps as the best type, containing the entire substance of beef and wheat-flour in rapidly diffusible and assimilable form. Extracts of meat were represented in various forms at the stall of Liebig's Extract of Meat Co. (9, Fenchurch-avenue, London, E C.) Amongst the new preparations added to the already excellent list is "Oxo" which, as we have shown in our analytical columns, is not a mere stimulant but a nutrient preparation also The Manhu Foods (88, Charing Cross-road, London, W C), are represented as diabetic foods though containing carbohydrates to the same degree as wheat flour because the starch is said to be changed in such a way that it is acted upon by the intestinal juices so completely as not to aggravate the condition of the diabetic These foods appear to have been tried by some physicians who report good results in spite of the theories held that carbohydrates should be excluded from the regimen of diabetic patients Similar arguments are advanced by the Cheltine Food Co , Limited (Cheltine Works, Cheltenham) who exhibited a number of foods of a special kind They hold that the starch of the cereals used is still starch, but that owing to a certain process of manufacture it may serve its normal purpose in the nutrition of the body of the diabetic patient instead of being excreted as sugar These statements seem to us to require very definite clinical confirmation A very great variety of special foods was shown by Bovril, Limited (152 to 156 Old street, City-road, London, E C) The preparations included raw meat juice as well as the extracts and also the emergency foods and rations which gave satisfaction in the South African war Close by was the exhibit of Virol, Limited, of 152 Old street, City road, London, E C We have already described this preparation which is composed of the proteids and fat of beef and eggs, the marrow of beef and extract of malt, all these being associated with their respective mineral salts which are of dietetic value Messrs Cadbury Brothers (Bourneville, Birmingham) exhibited their well known cocoa These manufacturers make special claim for the purity of their cocoa, the process of manufacture relating only to the fine grinding of high quality cocoa and the expression of a good deal of its indigestible fat We have already critically examined the special foods of Messrs Callard and Co (65, Regent-street, London, W), and invariably we have been enabled to confirm the special claims made for these foods, such, for example, as the food for the diabetic the food for reducing weight, the food for indigestion, and the food for the rheumatic and gouty A very satisfactory feature of Nestlé's condensed Swiss milk (H Nestlé, 48, Cannon street, London, E C) is the maximum proportion of fat which it contains, an average of just over 13 per cent The exhibit included condensed milk without sugar and a special food for infants We have published analyses of somatose, a tasteless and odourless powder made from beef and consisting largely of albumose The company (165, Queen Victoria street, London, E C) now prepare a fluid somatose which is more convenient for administration than the powder We have also described analytically Maggi's excellent consommé for the preparation of a nutritious soup It contains something more than the mere extractives of meat—in fact, the nutrient principles The tonic bouillon contains, as we have also shown, an assimilable form of iron Messrs J and G Cox, Limited (Eastcheap buildings, London, E C) exhibited their sparkling gelatin which is a pure product and reliable for dietetic purposes Besides the well known fluid malt extract, M Hoff (29, Newbury street, London, E C), exhibited liqueur ironol and Mattoni's iodine preparations Meat preparations were of course the feature of the exhibit of Messrs Brand and Co of Mayfair, London, W They showed raw meat juice as well as essences and peptones and a nutrient powder which we have already described in our analytical columns It is prepared from the fibre of muscle and contains the proteids unaltered and uncoagulated Messrs G Van Abbot and Sons (104, Wigmore-street, London, W) showed their various foods for diabetics, dyspeptics, and invalids, including the well known gluten bread, bran gluten rolls, soya bread, almond bread, and so on We note that they are introducing a new and cheap biscuit for diabetic patients called the Midolia biscuit In the analysis given of this biscuit the proteids are recorded together with the cellulose as 46 14 per cent This is a perfectly unintelligible association, proteids, of course, constituting flesh formers and cellulose being of no food value whatever Hence from this analysis the food value of the biscuit cannot be deduced

Next week we propose to give an account, amongst other things, of the interesting and novel series of sanitary appliances which were offered for inspection and which formed a very important and attractive feature of this year's exhibition

(To be continued.)

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY

THE eighth annual report and balance sheet of the London and Counties Medical Protection Society were received and adopted at the annual general meeting held at 12, New Court, Carey street, Lincoln's Inn, W C , under the presidency of Mr Jonathan Hutchinson, on May 28th Though the number of members present was only 17 considerable discussion took place before the adoption of the report

The annual report of the Council stated that the society had made very satisfactory progress both in numbers and in financial position A large number of members had availed themselves of the help of the society and the increasing number of members made the work considerably heavier As usual, a great many cases had been dealt with in which patients had tried to evade paying for the services of their medical attendants by alleging negligent or unskilful treatment As a rule, it had sufficed for the society to undertake the case for the fees to be paid forthwith Unceasing efforts had been made to suppress unqualified practice, but unfortunately the highly unsatisfactory state of the law enabled quacks to continue their evil practices with impunity The interests of the dental section had not been overlooked and a batch of dental cases will come before the next meeting of the General Medical Council in regard to unprofessional advertisements In accordance with precedent the Council did not publish details of cases in which the assistance of the society had been sought and obtained When a member of the society complained of unqualified practice in his own immediate neighbourhood the matter had been taken up and dealt with as one directly concerning the interests of the member The reserve fund had now nearly equalled a sum representing 15s for every member of the society, but it would, of course, have to be increased as new members joined

Dr L LIEBSTER commented on the very vague terms in which the report had been drawn up and asked for the number of the quacks who had been prosecuted by the society and also how many members there were in the society

This speaker was followed by Mr E R DAWSON who explained that it was difficult to get new members in his district because of the evasive and impotent reply that had been received from the society in answer to a letter asking for the prosecution of a quack. He had noticed that the Medical Defence Union not only secured the credit of doing a great deal of work but they took care to bring the facts well before the profession He was not at all satisfied with the attendance at that meeting and would like to know the number of members in the society so as to judge what percentage was present

Mr A G R FOULERTON (honorary financial secretary) stated that the number of members was somewhere between 1600 and 1700 and he suggested that it was possible to arrive at the number by calculating from the figures in the balance-sheet

Dr HUGH WOODS (general honorary secretary) replied at great length concerning the principles which governed the management of the affairs of the society by the Council He gave a brief sketch of the present position of the law as to medical practice and stated that the Council had not seen its way to carrying out the prosecution of a quack during 1900

Dr LIEBSTER said that he was quite satisfied and the accounts and balance sheet were unanimously passed The various officers of the society were re elected and the proceedings closed with a vote of thanks to Mr. Jonathan Hutchinson for taking the chair

ASYLUM REPORTS

Derby Borough Asylum (Annual Report for 1900).—The average number of patients resident during the year was 304 and comprised 143 males and 161 females The admissions during the year consisted of 94 patients—viz , 51 males and 43 females Of these nine—viz , five males and four females, were not first admissions Dr S Rutherford Macphail, the medical superintendent, states in his report that among the admissions were 10 patients from the union who were afterwards transferred from the pauper to the private class. Five males and four females among the admissions had formerly been under treatment in this asylum. "*Only* six of the nine cases were relapses after previous recovery; they had, on an average, kept well for four years and one month since their discharge." The mean age of the patients admitted was 43 years, the youngest being 16 and the oldest 82 years. Five of the patients admitted were transferred from other asylums and were all chronic cases. Forty-two per cent. of the admissions were cases of recent and, possibly, curable insanity, while the proportion of general paralytics was less than that of the previous year, but against this should be set the tendency each year to send in more senile and hopeless patients who hitherto would have been cared for in their own homes or in workhouses. Suicidal tendencies were present in 54 cases admitted, and 17 of these were actively suicidal and required constant watching to prevent self-destruction. Only eight of the admissions were in good or average bodily health, while four were admitted in a critical and almost moribund condition, and of these three died within a fortnight. Of the causes of insanity among the admissions alcoholic excess was found in 21 cases, influenza in 10, and old age in seven cases; 31 patients were predisposed to insanity on account of hereditary influences, and 18 had had previous attacks. The number of cases discharged as recovered during the year amounted to 34, or 11·1 per cent. of the average number resident. The number of deaths was 44—viz., 24 males and 20 females, or 14·4 per cent. of the average number resident. "Two-thirds of the deaths occurred in the first quarter of the year and were indirectly the result of a severe epidemic of influenza." General paralysis was the cause of death in 16 cases, or 36 per cent. of the total number of deaths. The average length of residence of these patients was under 10 months. Cardiac disease was responsible for four deaths and three patients died from phthisis. One case of suicide of a remarkable nature occurred and was the subject of a coroner's inquest. A female patient suffering from melancholia "tore out her tongue and threw it on the floor by the unaided use of her fingers." There was extensive bleeding which was soon controlled, but the shock was severe, and being a sufferer from heart disease she died 42 hours afterwards. "There had been no previous attempt at self-destruction by this patient, but she was regarded as suicidal." The possibility of such an occurrence had not been contemplated. "It was unfortunately impossible," says Dr. Macphail, "to prevent the other patients from hearing the details of a case of this sort, owing to the publicity given it by the local press. During the succeeding few weeks four of my actively suicidal patients told me they had tried, without success, to pull out their tongues." During the months of January and February a severe epidemic of influenza prevailed, affecting altogether 117 persons, including patients and staff. As compared with previous epidemics the symptoms and complications were chiefly abdominal; 41 per cent. of the patients and 30 per cent. of the staff were affected. A married woman who was admitted on March 1st (1900) was safely confined of a child on the 26th and she made a good recovery. Lectures and demonstrations by the medical staff are systematically given to the nursing staff. The Lunacy Commissioners in their report state that the institution is in a very favourable condition as regards management. In every case of death a post-mortem examination was made and the case-books and other medical records continue to be very well kept.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Brighton Urban District.—Dr. Arthur Newsholme gives some interesting tables in his current annual report as to the value of isolation hospitals in the control or limitation of the spread of scarlet fever. Such tables are of considerable value in view of the discussions which have recently taken place upon this subject. Scarlet fever prevailed in a mild type in Brighton last year and Dr. Newsholme asks whether, having regard to such mildness, the town obtains a *quid pro quo* for the somewhat heavy outlay which the machinery of control demands. He, however, answers the question unhesitatingly in the affirmative. He thinks that the isolation of scarlet fever cases in hospital tends to diminish the virulence of the disease and that such isolation, generally speaking, has had an influence in bringing about the present benign type of the disease. When, and if, the type of disease becomes more virulent there will not be wanting those who will allege that such virulence has been produced by aggregation in hospital. We cannot here reproduce all Dr. Newsholme's tables in this connexion, but those medical officers of health who take interest in this question may be glad to consult them. We present, however, one table relative to the differences in fatality-rate between cases treated at home and hospital isolated cases, and it has to be noted that the average is enormously in favour of the hospital.

Year.	Admissions to sanatoria per cent. of total notified cases.	Case mortality per 100 cases.	
		Among patients treated at home.	Among patients treated in sanatoria.
1891 (from March 1st)	70·0	—	—
1892	77·7	6·0	2·5
1893	70·6	2·5	1·6
1894	82·2	2·6	1·3
1895	77·4	2·3	2·6
1896	82·6	2·3	2·0*
1897	81·6	3·3	3·7
1898	82·7	3·1	1·6
1899	85·5	3·7	0·9
1900	87·8	5·6	1·7

* Including one death after the patient returned home.

Obviously patients are at times too ill to be sent to hospital, and in this sense the figures relative to the hospital cases are favoured, but, on the other hand, very severe cases are frequently sent to hospital on account of the better nursing to be obtained there, while among the cases treated at home are a large number of children of wealthy parents among whom the death-rate is likely to be but small. An interesting account of an outbreak of milk-borne scarlet fever is embodied in Dr. Newsholme's report. With regard to diphtheria tables illustrative of the relative prevalence of this disease among the scholars of the board schools and the voluntary schools are given, and the figures show a very considerable excess of attacks among the children in board schools—i.e., the excess in 1899 was 30 per cent. and in 1900 86 per cent. A table showing the age-incidence of diphtheria in relation to school infection is here reproduced:—

Percentage of Fatal Cases at each Age-group.

Ages.	Cases in which there was no school attendance.	Cases in which there was school attendance	
		(*a*) Including secondary cases.	(*b*) Excluding secondary cases.
0–3 ...	23·4	2·7	0·4
3–13 ...	34·3	89·2	93·7
Over 13 ...	42·3	8·1	5·9
—	100·0	100·0	100·0

The excess of diphtheria in some schools over that in others is, perhaps, Dr. Newsholme thinks, to be accounted for partially by the varying activity on the part of teachers to procure the return of convalescent children to school in order that the average attendance may be as little diminished as practicable. The experience of Brighton is, in common with practically all other towns, that diphtheria spreads largely by unrecognised cases and by what may be termed persistently infectious cases. As Dr. Newsholme observes, there is need for a much larger use of medical aid in determining why children are absent, and whether they may safely return to school; in other words, better machinery and increased expenditure are essential The voluntary notification of phthisis is now in operation in Brighton, the sum of 2s 6d being paid for each notification received, save in the case of a certificate from an official in his public capacity, when the fee is 1s On a case being notified the patient is visited by one of the medical officers of health, particulars are taken, and advice is given Japanese paper pocket handkerchiefs are left when required, and they seem to be appreciated greatly The experience of the year has been that the voluntary notification of phthisis can be worked without friction, and the patient, whose occupation has in no case been interfered with, has always been grateful for the advice given It is, however, sometimes found that when a second visit is made the house is occupied by new inmates who have taken up their quarters there before cleansing and disinfection have been accomplished A more rigid system of registering changes of address would assist administrative measures

Macclesfield Urban District —This district suffered somewhat heavily from enteric fever during 1900 and Mr J Hedley Marsh has been impressed with the high directly infective power of this disease under certain conditions He tells us that in one localised outbreak he traced no less than 75 per cent of the cases to direct infection, and in another outbreak he regarded 60 per cent of the cases as having been so caused He thinks that the delay in notification is largely responsible for the spread of the disease, and as the sanitary authority have now provided for the performance of Widal's test gratuitously doubtless the medical practitioners in the district will have any suspicious cases thus examined as early as possible

Crewe Urban District —Dr Alfred Greenwood refers in his annual report for 1900 to the large proportion which in this district still born children bear to the total number of births The annual rates for the last 11 years have ranged from 3 per cent to 5 8 per cent of the total births

Finchley Urban District —Dr Henry Kenwood, in making some observations upon the health of schoolchildren, strongly advocates the periodical inspection of the scholars by medical men in the manner which now obtains in Germany As an illustration of the advantages of this system mention is made of Leipsic where, as a result of the examination of the scholars in the schools, there were detected two cases of phthisis, 11 of heart disease, 10 of spinal curvature, 63 of obstructive growths in the nose and throat which led to defects in speech, 75 of defects of vision, and 10 of defects of hearing It is difficult to over estimate the advantages of a system such as this provided the defects found are properly dealt with The removal of adenoids alone would probably be productive of the greatest comfort and wellbeing to the children operated upon, and how much unnecessary strife may the defective vision and hearing have led to between pupil and teacher? We quite agree with Dr Kenwood that the arrangements *quâ* health protection for dealing with absentees might be enormously improved

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 33 of the largest English towns 6561 births and 3674 deaths were registered during the week ending May 25th The annual rate of mortality in these towns, which had been 16 5 and 16 8 per 1000 in the two preceding weeks, declined again last week to 16 7 In London the death rate was 15 7 per 1000, while it averaged 17 4 in the 32 large provincial towns The lowest death rates in these towns were 11 2 in Croydon, 12 1 in Norwich, 12 6 in Brighton, and 13 6 in Bristol, the highest rates were 21 5 in Swansea, 21 8 in Birmingham, 22 1 in Salford, and 22 6 in Wolverhampton The 3674 deaths in these towns last week included 388 which were referred to the principal zymotic diseases, against 394, 381, and 372 in the three preceding weeks, of these 120 resulted from whooping-cough, 93 from measles, 65 from diphtheria 49 from diarrhœal diseases, 38 from scarlet fever, and 28 from "fever" (principally enteric) No death from any of these diseases was registered last week in Huddersfield, in the other towns they caused the lowest death rates in Brighton, Norwich, Oldham, and Halifax; and the highest rates in Swansea, Wolverhampton, Salford, and Preston The greatest mortality from measles occurred in Portsmouth Nottingham, and Sunderland, from scarlet fever in Preston, from whooping-cough in Swansea, Wolverhampton, Derby, and Newcastle, and from "fever" in Wolverhampton The mortality from diarrhœal diseases showed no marked excess in any of the large towns [illegible] included 22 in London, four [illegible] three in Leicester, and three [illegible] small pox was registered last week in any of the 33 large towns; and no small pox patients were under treatment in any of the Metropolitan Asylums hospitals during the week ending May 25th The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2241, against numbers increasing from 1522 to 2052 on the four preceding Saturdays; 341 new cases were admitted during the week, against 371, 397, and 323 in the three preceding weeks The deaths referred to diseases of the respiratory organs in London, which had been 237 and 249 in the two preceding weeks, declined again to 191 last week, and were 98 below the corrected average The causes of 39, or 1 1 per cent, of the deaths in the 33 towns last week were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in Bristol, Bradford, Leeds, Sheffield, and in 14 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Blackburn, and Preston

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in the eight Scotch towns, which had been 19 3 and 20 2 per 1000 in the two preceding weeks, further rose to 20 7 per 1000 during the week ending May 25th, and showed an excess of 4 0 per 1000 over the mean rate during the same period in the 33 large English towns The rates in the eight Scotch towns ranged from 14 2 in Perth and 18 9 in Leith to 22 0 in Aberdeen and 23 6 in Dundee The 659 deaths in these towns included 40 which were referred to whooping cough, 30 to diarrhœa, 19 to measles, two to scarlet fever, two to diphtheria, one to small-pox, and not one to "fever" In all, 94 deaths resulted from these principal zymotic diseases last week, against 99 and 89 in the two preceding weeks These 94 deaths were equal to an annual rate of 3 0 per 1000, which was 1 2 above the mean rate last week from the same diseases in the 33 large English towns The fatal cases of whooping cough, which had been 49 and 41 in the two preceding weeks, further declined last week to 40, of which 19 occurred in Glasgow, 13 in Edinburgh, four in Leith, and three in Dundee The deaths from diarrhœa, which had been 20 and 18 in the two preceding weeks, rose again to 30 last week, and included 17 in Glasgow, three in Edinburgh, three in Dundee, three in Aberdeen, two in Paisley, and two in Perth The fatal cases of measles, which had decreased from 25 to 15 in the four preceding weeks, rose again last week to 19, of which 10 were registered in Glasgow, three in Greenock, two in Edinburgh, and two in Paisley The mortality from scarlet fever corresponded with that recorded in the preceding week, while that from diphtheria showed a marked decline The fatal case of small pox occurred in Glasgow The deaths referred to diseases of the respiratory organs in these towns, which had declined from 169 to 101 in the four preceding weeks, were again 101 last week, and were slightly above the number in the corresponding period of last year The causes of 24, or nearly 4 per cent, of the deaths in these eight towns last week were not certified

HEALTH OF DUBLIN

The death rate in Dublin, which had been 27 4 per 1000 in each of the two preceding weeks, declined to 26 4 during the week ending May 25th During the past four weeks the death rate in the city has averaged 26 9 per 1000, the rates during the same period being 16 0 in London and 21 5 in Edinburgh The 175 deaths of persons belonging to Dublin registered during the week under notice were seven below the number in the preceding week, and included nine which were referred to the principal zymotic diseases, against 15 and 10 in the two preceding weeks, of these, five resulted from whooping-cough, three from diarrhœa, and one from "fever" These 9 deaths were equal to an annual rate of 1 4 per 1000, the zymotic death rate during the same period being 1 9 in London and 3 3 in Edinburgh The fatal cases of whooping-cough, which had been seven and eight in the two preceding weeks, further declined last week to five. The three deaths from diarrhœa showed an excess over the number in the preceding week. The 175 deaths in Dublin last week included 28 of children under one year of age and 45 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a slight decline from the numbers recorded in the preceding week. Five inquest cases and three deaths from violence were registered; and 66, or more than one-third, of the deaths occurred in public institutions. The causes of nine, or more than 5 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

Royal Navy Medical Service.

Deputy Inspector-General of Hospitals and Fleets Thomas Bolster has been promoted to the rank of Inspector-General of Hospitals and Fleets in His Majesty's Fleet.

Royal Army Medical Corps.

Civil Surgeon James Bertram Clarke to be Lieutenant.

Major A. O. Fitzgerald has taken over medical charge of the Station Hospital and troops, &c., Golden Hill Fort, Isle of Wight. Surgeon-Captain Smith, A.M.R., assumes medical charge of troops, Buddon Camp. Surgeon-Captain A. Macdonald, A.M.R., proceeds to the Station Hospital, Edinburgh Castle, for duty.

Army Medical Reserve of Officers.

Brigade-Surgeon-Lieutenant-Colonel Henry William King, 2nd Volunteer Battalion the Cheshire Regiment, to be Surgeon-Lieutenant-Colonel.

Volunteer Corps.

Artillery: 4th Durham (Western Division, Royal Garrison Artillery): John Stewart Milne to be Surgeon-Lieutenant. 1st Norfolk (Eastern Division, Royal Garrison Artillery): Alexander Michael Ross to be Surgeon-Lieutenant. *Royal Engineers:* 1st Sussex: Robert Macfie Johnston to be Surgeon-Lieutenant. *Rifle:* 1st Volunteer Battalion the Essex Regiment: James Aitken to be Surgeon-Lieutenant.

The War in South Africa.

It must be confessed that to the ordinary reader in this country it is very perplexing and difficult—even with the aid of Lord Kitchener's laconic despatches and a good map—to follow out the military policy and course of events in South Africa. We hear of sweeping movements in this direction and that and we get summary statements from time to time of the captures effected by the British columns and of huge losses by the Boers in horses and live stock and in ammunition and food stuffs until the wonder is that any ammunition is left for the Boers to fight with or that anything is left for them to maintain a separate existence in the field. The extent and nature of the country are eminently suited, of course, for the Boers' elusive tactics, who at once split up and retire on the approach of a British column only to emerge again as soon as it has departed. It seems still to be the case that our forces have not sufficient mobility to catch the Boers, nor is this to be wondered at considering the distances that have to be traversed. Our possession of the railway is a great factor in our favour, but apart from the frequent raids made upon it by the Boers much of the fighting and many of the skirmishes are not along, or in the vicinity of, the track of the railway, and the number of horses required to mount our troops and to keep them moving in pursuit of the enemy is enormous. The following is an extract from a letter received by a member of our staff from a private in the Cameron Highlanders. The particular "Tommy Atkins" in question, who is evidently a rather observant person, bears out the views so frequently expressed in The Lancet.

> Sir,—There is a lot of *mounted troops keep* coming out here and the public think we should send troops home in return. I don't; there is not enough out here yet, the more troops the quicker it will be finished and will be cheaper in the end. Infantry is no use now only for guarding convoys and the railway. It is a very bad country and I am sure if people at home was but here to see it they would open their eyes.

The Boer leaders, whose names are by this time as familiar as household words with the British public, disappear and reappear on the scene of action in a somewhat perplexing way. They are neither caught nor do they surrender. Meanwhile, so far as the Orange River Colony is concerned, we really seem to be getting its civil administration into working order, and for the rest of the country we have only to possess our souls in patience and to await a possible sudden and unexpected collapse or a slow disintegration in the way of inanition of the force fighting against us. The lists of wounded which appear from time to time show that a chronic "sniping," alternating with an occasional acute engagement or skirmish, is still going on and that enteric fever holds an important place among the diseases of the army in the field. Happily, plague makes but slow progress and we do not hear of any severe outbreak or recrudescence of that disease such as has been recently reported to have occurred at Hong-Kong.

The Post-Graduate Education of Naval Surgeons.

The April number of the *Archives de Médecine Navale* contains an appreciative notice of the recommendations made by the commission which was recently nominated to report upon the system of instruction in vogue at Haslar. "In its very interesting report," says the author, Dr. Portengen of the Dutch navy, "the commission in the first place insists upon the insufficiency of the existing cours in so far as concerns the diagnosis and treatment of th tropical diseases which are to be met with at exoti stations." The attention of the commission had naturall been called to the School of Tropical Medicine recentl established near the Albert Docks under the auspices of th Colonial Minister, but in its opinion the instruction at tha institution lasted too long for the purpose in hand, and moreover, included subjects, such as gynæcology, that wer unsuitable. The several additions recommended by th commission to the Haslar course as it now stands—i e tropical pathology, blood analysis, and serotherapy—mee with the writer's unqualified approval, as does the pro posal to establish special wards for men suffering from diseases that were acquired abroad. Dr. Portengen likewis thinks well of the stress laid upon the following subjects removal of sick and wounded men; naval surgery; the equipment of hospital ships; and the application of the Roentgen rays. The extension of the course to four month and the appointment of an additional professor he regards as sufficient; and he approves the suggestion of offering special prizes for the encouragement of zealous students. Finally, he mentions with commendation the commission's advice regarding the supply of instruments for medical officers at a cost of 500,000 francs. The sole unfavourable criticism in this exhaustive article has reference to the omission of provision for an electro-technical examination in cases of beri-beri, "which," says Dr. Portengen, "is such a very valuable procedure."

Deaths in the Services.

Inspector-General William Kilner Swettenham (retired list), A.M D., at his residence, in West Kensington, on May 21st, aged 84 years. He joined the army April 9th, 1841; became surgeon Oct. 14th, 1851; surgeon-major April 9th, 1861; and retired as inspector-general June 27th, 1868. He served with Havelock's column in the action of Mungarwar, attack and capture of the Alumbagh, the assault and relief of the Residency of Lucknow and its subsequent defence, and was wounded (grant of a year's service). He was present with Outram's Division throughout the occupation of the Alumbagh and also at the capture of Lucknow by Lord Clyde, and the subsequent campaign in Oude, including Buxar Ghat and Doondiakera (medal with two clasps).

South African War Notes.

Lieutenant P. G. Stock, R.A.M.C., is reported dangerously ill with enteric fever at Charlestown (May 26th).

Major Thomas, R.A.M.C., has left England for the seat of war in charge of a large draft of non-commissioned officers and men of the Royal Army Medical Corps.

The Royal Albert Hospital, Devonport.

The recent bazaar held in aid of the funds of this hospital realised over £700, and after paying expenses leaves £635 for the benefit of the funds of the institution.

Captain F. E. Gunter, R.A.M.C., has been granted a gratuity of £250 yearly by the Government of India on account of an ailment contracted by him in the performance of his duty in August, 1897.

Lieutenant-Colonel W. Johnston, who has been for over a year officiating as Assistant Director, A M S, has retired from that hospital

Major G H Barefoot, R A M C, and Lieutenant McGregor, R A M C, have been appointed principal medical officer and assistant principal medical officer respectively at the Royal Military Tournament

Correspondence.

"Audi alteram partem."

THE NATIONAL HOME READING UNION.

To the Editors of THE LANCET

SIRS—Had it not been for the war in South Africa and the great national bereavement there can be little doubt that the celebration of the millenary of King Alfred's death would have been one of the most notable events of the year Yet although the celebration cannot now attain to the importance as a national festival which its promoters originally contemplated, no passing events can rob it of its significance, nor is the city of Winchester, in which the representatives of universities and learned societies will shortly assemble, any less interesting as the capital of the great king Its thousand years of association with his name and fame make it in a peculiar sense the birthplace of English national life, and its abundant historic monuments mirror the successive developments of this life with very singular fulness Will you allow me to call the attention of your readers to the summer assembly which the National Home Reading Union has arranged to hold at Winchester from June 22nd, when the Mayor has kindly promised to welcome the visitors until June 29th, when the members of the assembly will disperse, visiting Athelney, King Alfred's refuge in his darkest days, or Wantage, the scene of his decisive battle with the Danes, on their way to their respective homes? During the week lectures will be given by Dean Stubbs, author of "God's Englishmen the Prophets, and Kings of England", the Bishop of Bristol on "King Alfred [illegible] Professor Skeat, [illegible] Edward VII", [illegible] ng of the West [illegible] nchester Cathedral', Mr N C H Nisbett, on "Wolvesey Castle", Dr T J Lawrence, some time deputy Whewell Professor of International Law at Cambridge, on "Alfred as Statesman and Lawyer" (four lectures), Mr Philip Wicksteed, on "Alfred as a Man of Letters" (four lectures), Mr J E Marr, F R S, Sec G S, on "The Application of Geology to Scenery" (four lectures); and others

The course last named indicates a secondary purpose of the meeting—namely, the study of the geology and botany of the district as well as its archæology The afternoons of the assembly will be devoted to visits to the places and [illegible] the great king's fame, as well as [illegible] morials of mediæval times with [illegible] ds such, for example, as the [illegible] Hyde Abbey, and the Hospital of St Cross where the "Wayfarer's Dole" of bread and beer is still given to strangers who ask it The assembly is open to all who obtain tickets from the Secretary, National Home-Reading Union, Surrey House, Victoria Embankment, W C

I am, Sirs, yours faithfully,

ALEX HILL,
Master of Downing College, Cambridge.

Surrey House, Victoria Embankment, London, W C,

"HÆMORRHAGIC TYPHOID FEVER"

To the Editors of THE LANCET

SIRS—Having once attended a case of hæmorrhagic disease I am inclined to think with Dr Eshner that its pathology more often points to a degraded state of the blood and blood-channels than to the toxic effect of alcohol or, indeed, any other condition The case was one of small pox and the horrible appearance of the body both before and after death is an experience not easily forgotten The whole surface of the body was of a blue or rather prune juice colour There was a very low temperature and death took place in something under two days He was a quiet, respectable man and had no history of either alcoholic or other excess On account of the panic raised in the place we buried him in the dead of night under, I must say, rather [illegible] Mr George Ormsby, now of Runco, [illegible] in the case, I have no doubt [illegible] or it was of a very startling character and one not often coming within the ken of even the busiest practitioner

I am, Sirs, yours faithfully,

Kettering May 25th, 1901 **JAMES MORE**

"LOCAL *v* GENERAL ANÆSTHESIA IN CERTAIN CASES OF ABDOMINAL SURGERY."

To the Editors of THE LANCET

SIRS,—Mr T. H Morse's remarks in THE LANCET of May 11th, p 1322, raise the interesting question of shock in cases of abdominal operations and the part, if any, which anæsthetics play in producing shock Few surgeons, I imagine, certainly few anæsthetists, will agree with Mr Morse in placing the anæsthetic first as a cause of shock It is open to doubt whether there ever is a patient on whom it is safe to operate but whom it is unsafe to anæsthetise To begin with, death from shock of operation was no unknown thing before the introduction of anæsthetics, but death from shock due to an anæsthetic alone, other than chloroform, is so far, I believe, unrecorded Therefore we know that operations alone can kill by shock, we have no evidence that ether alone can do so Again, it is, as your correspondent Dr S H Long[1] points out, not uncommon to administer anæsthetics to a collapsed patient and to notice the general improvement of circulation and improvement under the influence of the anæsthetic The main factors, I believe, in the production of shock are the severity of the operation and the time taken in its performance It is only by dulling the surgeon's appreciation of the value of rapidity in operating that anæsthetics can be blamed for the production of shock Since the introduction of anæsthetics surgeons have naturally become more indifferent to the length of time which they occupy in performing operations, yet this has a most important bearing on the patient's chances of recovery The anæsthetic chosen also, no doubt, makes a difference. Chloroform by the lowered blood pressure it induces probably adds to the facility with which shock may be produced. Ether, on the other hand, will often render operation safely possible on a patient who might otherwise succumb from shock Long administration of ether probably adds to the chance of the patient's dying after the operation when reaction from the too prolonged stimulation sets in That is another matter and is avoidable by proper discrimination in using anæsthetics The danger of inhalation of vomit which Mr Morse refers to is completely avoidable by proper washing out of the stomach before operation and if necessary again later This can easily be performed while the patient is anæsthetised without prolonging the anæsthesia, as I have pointed out[2] In the abdominal operations which I have seen performed under local anæsthetics though no pain was felt the reflex effects of manipulation of abdominal contents were enough to impede the surgeon and to distress the patient, and shock was certainly no less than it would have been under general anæsthetics properly chosen and administered To what extent the chance of shock varies with depth of anæsthesia is uncertain, but whether shock is less likely under deep anæsthesia or under light, at any rate evidence seems to show that shock is less likely under general anæsthesia suitably produced and maintained than altogether without it

I am Sirs, yours faithfully,

Sloane-terrace Mansions, S W, May 23th, 1901 **J BLUMFELD**

"THE METROPOLITAN WATER-SUPPLY."

To the Editors of THE LANCET

SIRS,—Will you allow me to point out, in connexion with your annotation on water supply in THE LANCET of May 18th, that the figure quoted for filtration—viz, 1 12 gallons per square foot per hour—is the least rapid instead of being, as stated, the most rapid of all the companies, and that the use of such language as "the dirtiest water" is not justifiable, considering that the differences in colour, like those in analysis, are in measurements absolutely unappreciable except by scientific method. I inclose the official report for March and remain, Sirs,

---

[1] THE LANCET, May 25th, 1901 p 1493.
[2] THE LANCET, Sept. 23rd, 1899, p. 833

Yours faithfully,
J. GOODWIN, Secretary.

Grand Junction Waterworks Company, South Molton-street, London, W, May 22nd, 1901.

⁂ We much regret that through an unfortunate oversight we stigmatised the figure quoted for filtration of the Grand Junction water (namely, 1·12 gallons per square foot per hour) as "the most rapid of all the companies." As a matter of fact, the rate is the least rapid. But it is not correct to say that "differences of colour, like those in analysis, are in measurements absolutely unappreciable *except by scientific method*." The dirty colour of the water supplied by some of the metropolitan water companies can frequently be detected by the simple method of inspecting it in a glass water-jug or tumbler. Anyone who is supplied by the Lambeth, the Southwark and Vauxhall, or the Grand Junction Companies can easily satisfy himself on this point by examining the water which he receives after the Thames has been in flood for a few days. Dirt has been defined as matter in the wrong place, and the matter which causes the brown tint is decidedly out of place in drinking-water. The word dirt is accurately applicable to the matter which is brought down by the Thames water when the river is in flood, and which, when not removed by the process of sedimentation and filtration by the water companies, is supplied by them in the water which they distribute to their customers. In the case to which the secretary refers, in which brownish water was distributed by the Grand Junction Company, it is evident that the failure to purify the dirty Thames water was not due to hurried filtration, as we had previously assumed in error; it must therefore have been due either to some other error in the process of filtration or to the fact that the storage reservoirs are totally inadequate to allow a sufficient time for the preliminary process of sedimentation.—ED. L.

"LEGISLATION AGAINST NATIONAL INTEMPERANCE."

To the Editors of THE LANCET.

SIRS,—It would be highly interesting to learn exactly what are Dr. Archdall Reid's real views respecting the relations of his theory of alcoholic immunity to Weissmann's speculation. In one case he appears as a Weissmannian out and out; in another he figures as an opponent of the view that it is the germ plasm alone which can transmit features from one generation to another. Might I recommend to those of your readers interested in the question of heredity a perusal of two works which will show them how very far from being accepted by biologists are Weissmann's views. The one is a little book by Hertwig, "The Biological Problem of To-day" (Heinemann), the other, Cunningham's translation of Eimer's "Organic Evolution" (Macmillan). Herbert Spencer has declared himself dead against Weissmann's views. His pamphlets are published by Williams and Norgate. If Dr. Reid (or anybody else) is going to build up a serious theory of heredity with Weissmannism as its basis, I warn him that he is constructing a house of cards and nothing more. Cunningham well asks: "Is there any criterion by which we can distinguish among variations appearing *de novo* at a post-embryonic period of life, those which are acquired, and those which are due to variations of the germ plasm? There is none, and therefore it would be as true to assert that there is no evidence of the inheritance of any individual variations as to say there is no evidence of the inheritance of acquired variations." This is a sufficient answer to Dr. Reid and others who desire to lay the whole burden of proof that acquired variations can be inherited upon us. There is evidence, only they will not study it, as far as I can observe. What we of the neo-Lamarckian school believe is not that all acquired variations can be or are inherited, but that such variations may be inherited. The first difficulty of the Weissmann theory is to show that the germ plasm is really separate from, and independent of, the body of which it forms part. I have been looking for years for evidence of this fundamental proposition of the theory. It has not yet been supplied. That is why all the rest of the superstructure is in a highly rickety state. Hertwig's account of the experiments of Wilson and others on division of the eggs of echinoderms and frogs and the subsequent results of the development of the embryos give the death-blow to the notion that the germ plasm is one thing and the body plasm another. Dr. Reid will find a fuller account of such experiments in Wilson's large book on the "Cell" (Macmillan). One last point. Weissmannism applies itself to explain the continuity of amœba plasm, equally with the germ plasm of man. Now Vöchting, cutting a piece out of the middle of a thallus of Lunularia vulgaris, chopped it up with a knife into pulp. Spread on moist sand, the pulp gave origin to any number of young fronds. Is there any distinction between germs and body plasm, then, in lunularia? I trow not; and if not in lunularia, then the theory of Weissmann cannot hold good for all organisms. It is cases like this one which, to my mind, reduce Weissmann's doctrine itself to a mass of illogical pulp. I see that Dr Reid is to deliver a series of lectures on "Heredity" in Edinburgh. They are sure to be interesting and I hope he will publish them to enable us to understand his real relation to the biological theory under discussion. All I can say is that if no acquired characters can be inherited evolution becomes a mere farcical speculation, inheritance a theoretical fable, and all social reform, not to speak of medical teaching, a vain thing. I am, Sirs, yours faithfully,

Edinburgh, May 25th, 1901. ANDREW WILSON

THE COVENTRY PUBLIC MEDICAL SERVICE.

To the Editors of THE LANCET.

SIRS,—The ninth annual meeting of the Coventry Public Medical Service has just been held and the reports show a steady increase in membership. The number on the books is about 9000 and the collections for the year amounted to £1835 12*s*. There are 11 medical men on the staff who have the management entirely under their own control. It has been established on the wage basis principle and, broadly speaking, it works with success. This is the largest agency, we believe, under professional control for administering medical relief to the working classes and our experience on the wage limit question ought to be of some use to the profession at large We have proved by a practical working scheme how it may be carried out. There is no absolutely perfect plan by which dispensaries or other institutions can be managed Under any arrangement abuses will creep in, and although we do not adopt any strict detective system we do claim that under our system abuses are reduced to a minimum. Occasionally people are admitted whose incomes are above our limit, but we are always able to detect gross cases of abuse, and, approximately speaking, we enrol only the class of people for whom the service is intended. We have established a scientific branch for discussing questions of a medico-chirurgical character to which all eligible medical men in the neighbourhood are invited.

I am, Sirs, yours faithfully,

May 26th, 1901. W. RICHARDSON RICE, M.D. Dub.

"NEW YORK INSTITUTE OF SCIENCE."

To the Editors of THE LANCET.

SIRS,—Copies of the inclosed circular are being sent broadcast over this country, and judging from the number of letters I have received on the subject I fear they are having the effect anticipated by the senders—the exploitation of the British public for the benefit of an unscrupulous set of adventurers. My name is mentioned in these papers as practising hypnotism, and therefore, as it were, giving support to this institute; hence the inquiries like the one inclosed addressed to me. I need hardly say that I know nothing about these people. The more we know about hypnotism and the greater our belief in it as a therapeutic agent in competent medical hands the less likely are we to approve of this wholesale method of encouraging the use of hypnotism by the general public. I have seen the course sent to inquirers on paying five dollars. The fee is exorbitant for the information given, but the teaching inculcated is, I consider, fraught with danger to public morality.

I fear this unscrupulous exploitation of hypnotism will lead to the occurrence of such crimes against the person and pocket as are described in your annotation in THE LANCET of May 18th, p. 1419, "Suggestion and Hypnotism in their Relation to Jurisprudence," on Dr. von Schrenk-Notzing's article. It is to be hoped that medical men everywhere will lend their influence to counteract the work of this bogus institute.

I am, Sirs, yours faithfully,
CHARLES LLOYD TUCKEY, M.D. Aberd.
Park-street, W., May 26th, 1901.

*** The circular justifies Dr. Lloyd Tuckey's description of it as "unscrupulous exploitation of hypnotism."—ED. L.

"THE MEDICAL PROFESSION AND THE FRIENDLY SOCIETIES."

To the Editors of THE LANCET.

SIRS,—I cannot altogether agree with "Colliery Surgeon's" letter. I am of opinion that if friendly societies paid 4*s.* per annum for adult male members and 5*s.* for juveniles and female adults the friction between the friendly societies and their surgeons would at once cease. This is really the cause of dispute. Surely this sum is a reasonable one. The difficulty we have to contend with is that friendly societies insist on our acceptance of a halfpenny a week for juveniles and 3*s.* 6*d.* or 4*s.* for female adults. This is not a living wage and is the bone of contention between the profession and the friendly societies. The Long Eaton (Derbyshire) friendly societies intend to start an institution, and to give an instance of the determination and unanimity of the club officials interested in the promulgation of the scheme they have decided to have a house-to house canvass and to petition Sir Walter Foster to support the scheme. Mr. Gretton, M.P., has also been written to on the same question—viz., "Is it advisable to establish a friendly society's dispensary?" This means that in a town of 10,000 about 2500 belong to clubs, and if an institution of this kind is established all the married adult lodge members will put their wives and children in, thus increasing the number of dispensary members so considerably that of the eight town practitioners three or four will have to seek fresh fields and pastures new, for one man will have a fixed salary with free residence and have to do the work of two or three men. The general medical practitioner with clubs is better qualified to speak on this question than any member of the General Medical Council, the members of which have very probably never had a club appointment of any kind. It is only in places where the clubs have refused a fair fee that these institutions have been started.

I am, Sirs, yours faithfully,
Derby, May 12th, 1901. W. H. JACKSON, M.B.

TEMPORARY ARMY RANK FOR VOLUNTEER OFFICERS.

To the Editors of THE LANCET.

SIRS,—Perhaps Mr. MacNeill or one of the service Members would, at the earliest opportunity, ask Mr. Brodrick if, in view of army order dated May 15th, 1901, wherein temporary army rank is conceded to militia officers employed during the present emergency, a like privilege will be accorded to other auxiliary officers—viz., volunteer officers, combatant and otherwise, "doing duty with troops." Such a concession should at least be granted to those officers holding commissions in the Reserve and Army Medical Reserve; at any rate, they should be allowed seniority from the date of their reserve commissions. If it is just and necessary to grant temporary army rank to volunteers serving abroad it is equally just and necessary to do so for home service; and, further, if in view of the withholding of the gratuity to which they are entitled at the end of 12 months' service, until their services are dispensed with, any grant is likely to be made for "wear and tear" of uniform. Undress uniform, which in the ordinary course of volunteer duties lasted for years or even perhaps for the whole of a volunteer career, is now worn and dirty and must be replaced.

I am, Sirs, yours faithfully,
V. M. S.
May 25th, 1901.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Decline of the Plague in India.—Disturbances in the Punjab.—The Increase of the Famine.—Fresh Hospital Accommodation in Calcutta and Darjeeling.

THE decline of plague is not general throughout India although the total mortality was 3298 as compared with 4093 last week. The number of deaths is nearly double that for the corresponding week last year. The deaths last week fell in Bengal (districts) from 1707 to 1198; in the Punjab from 547 to 524; in the North-West Provinces from 424 to 287; and in Calcutta from 215 to 156. On the other hand Bombay city shows a rise from 393 to 419, Karachi city from 270 to 297, Kashmir (Jumma) from 23 to 46, and Gaya from 320 to 518. The disease still lingers in the districts of the Bombay province—Belgaum, Dharwar, Thana, and Cutch, as well as in the Mysore State. There have been 12 deaths from plague in Agra. This is a new outbreak and it shows how the disease is gradually diffusing itself over the whole country. A recrudescence of plague in Bombay city seems to attain a greater height, to last longer, and to subside more slowly than in any other city. The general mortality in Bombay keeps up at the rate of over 90 per 1000 per annum. Out of 1390 deaths for the week ending April 30th 403 are recorded as due to plague. Deducting this number from that of the general mortality it would still show Bombay with a death-rate of over 64 per 1000 per annum. As there is very little cholera or small-pox in the city, the excess mortality is imperfectly accounted for.

In the plague stricken villages of the Sialkot district of the Punjab there have been serious disturbances and troops have had to be despatched to them. The hospital assistants suffered severely at the hands of the mob and the Naib-Tahsildar was beaten and his thatched huts were ignited. No Europeans were attacked except the assistant commissioner who was pelted with stones and mud. Punitive police will now be placed in the district.

The latest famine returns show that there are still nearly 300,000 persons on relief and the numbers have been increasing lately in the Bombay Presidency. In the native States there are 30,000 and in Hyderabad Deccan about 25,000.

With the increasing popularity of Darjeeling as a hill station and health resort additional provision has to be made for the sick. A new surgical ward has been added to the Eden Sanitarium "for the separate and special treatment of serious surgical, medical, and obstetrical cases demanding operation and special nursing." The new block of the Presidency General Hospital in Calcutta ought also to be ready in a short time. It is intended primarily to afford medical aid and accommodation to well-to-do middle-class European inhabitants of Calcutta, and to planters especially.

May 9th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Hospital Saturday Fund.

THE annual meeting of the Executive Committee was held on May 20th. The report showed that the total receipts in respect of last year's collection were £18,280 7*s.* 10*d.*, of which sum £17,874 1*s.* 7*d.* were received from manufactories and industrial establishments. This showed an increase over the previous year. The expenses of collection amounted to 4·69 per cent.; the number of establishments contributing was 1802. Of the amount collected £10,000 were distributed among the medical charities of the city. Four convalescent homes were associated with the movement, being supported by these funds.

Report of the Medical Officer of Health.

The annual report on the health of the city for the year

1090 has just been issued by Dr. Alfred Hill. Some interesting details are given at length. The sanitary questions discussed in the report relate to the reforms required, to those already accomplished, and to the possibilities of increased action in the future. One fact is made evident—that the death-rate of the city is too high, being above the average for the last 20 years. Inquiry shows that this is mainly due to long-standing causes, among which are overcrowding and the existence of insanitary conditions in the poorer dwellings; it is demonstrated that in six of the wards the death-rates are considerably in excess of the rate for the city as a whole. Dr. Hill, however, justly remarks that while many of the older houses are unfit for habitation it is undesirable to close any large number of them until suitable new houses have been erected. Much has been done by the Health Committee in cleansing courts, improving drainage, and generally diffusing knowledge of the laws of health among the poorer classes, and efforts continue to be made to keep the public attention directed to the subject. In a previous communication mention was made of a threatened action for libel upon the chairman of the Health Committee in connexion with some articles published in the *Birmingham Daily Gazette* upon the slum question. It is now stated that a writ has been issued claiming damages for libel against this paper. Counsel have been retained on behalf of the plaintiff, Alderman Cook, chairman of the Health Committee.

Adulteration of Butter.

At the police-court recently certain tradesmen were summoned for selling butter containing 70 grains per pound of boric acid and at least 6 per cent. of water in excess. It was stated that the butter came from Australia and was then dealt with by some operation of the defendants. The question of excess of moisture has been raised before the Longton stipendiary who refused to state a case. In this instance the case was adjourned pending an appeal.

General Hospital, Birmingham: Past and Present Residents' Club.

A most successful dinner of past (since 1891) and present residents of the Birmingham General Hospital was held at the Great Western Hotel on Friday, May 10th, 46 attending (including late "residents" from Edinburgh, Leeds, Manchester, Derbyshire, Hereford, and London), while 26 others wrote expressing approval. Dr. T. Sidney Short occupied the chair. It was decided to form a club of all residents since January, 1891, to which all past and future residents would be admitted on application. An annual dinner is to be held in April or May. All past residents of the "General" wishing for further information are invited to communicate with the secretaries, Dr. W. J. McCardie, 54, Newhall-street, or Mr. Howard J. Collins, General Hospital, Birmingham

May 28th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Liverpool and District Branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis.

A MEETING of the executive committee of the above branch was held on May 23rd at the Medical Institution under the presidency of Mr. Edgar A. Browne. The chairman said that they were all agreed as to the object of the parent association in London, which was primarily the prevention of consumption. Those of them who belonged to the medical profession could now assure the general public that consumption was a preventable and transmissible disease, and that if they could only follow the teachings of science and use such precautions as the medical profession were able to suggest that which some quarter of a century ago was regarded as a disease inherited from the parent by the child, and as handed down from generation to generation, had now been proved to be as easily preventable as any other contagious or noxious disorder. Moreover, it had been discovered by the exercise of common sense as well as by the exact modes of observation which now existed that in many cases of consumption the patients made exceedingly good recoveries. The methods by which they proposed to reach the masses were by the education of public opinion, by means of lectures given by medical men of known standing and approved by the committee, and by the distribution of various kinds of useful literature. They also wanted to invite the coöperation of the municipal bodies of the towns. He might say with some satisfaction that there had been no necessity for them to invite the cooperation of the municipality of Liverpool. The Health Committee, the ex-Lord Mayor (Mr. Cohen), and the medical officer of health (Dr. E. W Hope) had thrown themselves into the movement with enthusiasm; they had been leaders in the work and there was no town in the whole kingdom which had made such practical progress in the matter as had Liverpool. Two large sanatoria were in course of erection in healthy neighbourhoods in the vicinity of the city. One, containing 60 beds, was being erected near Delamere Forest by private subscription and was intended for the treatment of early cases of consumption amongst the working-classes. This, it was hoped, would be ready for occupation in a few months. The second sanatorium was being erected on the banks of the river Dee, near Heswall, for the treatment of early cases amongst the poorer classes. The Health Committee had also adopted a new system of voluntary notification of consumption and they had also established depôts for sterilised milk. The demolition of insanitary property and the erection of better houses for the poorer classes were also means adopted by the corporation for the prevention of this fell disease. Sir John Willox, M.P, was appointed to be the chairman of the Liverpool branch of the association and Dr. William Carter was elected to the vice chair. Sir John Willox, Dr. William Carter, Dr. E. W. Hope, Dr. James Barr, Dr. T. R. Bradshaw, Dr. Nathan Raw, and Councillor Shelmerdine were chosen to represent the branch at the national meeting to be held in London in July.

The David Lewis Northern Hospital.

The vacancy at the David Lewis Northern Hospital caused by the resignation of Dr. Edward H. Dickinson is exciting much interest and will be keenly contested. The election, which is fixed for June 4th, will be made by a committee comprising 150 trustees of the charity. Dr. Dickinson was formerly lecturer in comparative anatomy and zoology at the Royal Infirmary School of Medicine prior to its incorporation with University College and was exceedingly popular with the students. He also took a great interest in the deliberations of the British Medical Association as a member of council. His resignation is much regretted by his colleagues, especially as he has not yet reached the specified age of retirement.—Mr. Benn W. Levy, with characteristic liberality, has offered to present the David Lewis Northern Hospital with the apparatus for the light ray treatment of lupus (Finsen). It is estimated that the cost of installing one lamp supplying four telescopes, together with the necessary accessories, will be about £1200. Mr. Levy has also undertaken to defray the expenses involved in working the telescopes during the space of a year.

The New Foundations in the School of Tropical Medicine.

The "Walter Myers Chair of Tropical Medicine," recently founded in commemoration of the late Dr. Walter Myers, has been bestowed upon Major Ronald Ross, F.R S., late I.M S, the lecturer on tropical medicine. Dr. J. E. Dutton has been appointed to the "Walter Myers Fellowship in Tropical Medicine," an institution which has been endowed for five years.

The Medical Faculty of University College, Liverpool.

The winter session of the Medical Faculty of University College will be inaugurated on Oct. 12th, when the opening address will be delivered by Dr. Oliver Lodge, F R.S, the principal of Birmingham University, and until recently the professor of physics at University College, Liverpool.

May 28th.

WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Housing of the Poor in Bristol.

THERE was established in Bristol a few years ago a committee for promoting the better housing of the poor, and it has quietly accomplished a great deal of good, principally in the way of obtaining the repair of dilapidated cottages or the closing of those which were beyond repair. At the annual meeting of the committee held on May 24th Mr. Lewis Fry raised a warning note with regard to the provision by municipalities of working class dwellings the rentals of which were not sufficient to pay the interest and repayments upon the original outlay It was a question, he said, whether they might not create a privileged class who would hold their dwellings at a low rental by the taxation of the whole community, and that possibly that class might be banded together and use their votes simply to protect themselves Mr Fry further deprecated the driving of private and voluntary enterprises out of the field The housing of the working classes is not quite so simple a matter as some ardent reformers would have us believe

Hospital for Pontypool.

Pontypool is the centre of a mining population approaching 50,000 in number and is situated in one of the Monmouthshire valleys, which is increasing almost as rapidly as some of the Glamorganshire colliery districts The nearest accident hospital to Pontypool is at Newport, and to this institution patients have to be taken a distance of some 12 or 15 miles, so that it is hardly surprising to find that there is a movement to establish a local cottage hospital. The initial steps were taken several months ago and the promoters have succeeded in obtaining as a free gift a freehold site of two and a half acres A bequest from the late Mr Cosslett of Bristol of £1000, with an annual grant of £100, has been secured. Yearly subscriptions amounting to about £700 are promised, while the workmen have agreed to contribute 1*d* weekly and the colliery proprietors offer another 1*d* per week for each man employed by them. The scheme is therefore well on the way towards realisation and plans have been prepared for a building with accommodation for 20 beds Although colliers as a class are somewhat averse to being treated in a hospital—or, perhaps, it would be more correct to say that the collier's wife *does* not like her husband to go to a hospital—it has been found that this aversion speedily disappears in those localities in which hospitals have been established, and at Aberdare, Mountain Ash, Porth, and Bridgend the accident hospitals are of immense service to the inhabitants

Refuse Destructor for Taunton.

The corporation of Taunton have led the way in so many municipal enterprises that a refuse destructor might be expected to be already installed in the town The first step towards the erection of what is considered an essential to the proper equipment of a public health department has now been taken and the Local Government Board have been asked to sanction the expenditure of £4500 upon a destructor to be erected at the sewage works. Taunton was the first municipality in England to establish electric lighting works, and at the present time extensive alterations are going on at the sewage works to adapt the mode of treatment to the septic tank method

Ambulance Arrangements at the Royal Agricultural Show.

One of the features of the Eisteddfodau which are held in different parts of Wales has of late years been the ambulance competitions and the instruction in first-aid provided in the technical instruction classes organised by several county councils The Glamorganshire County Council give special encouragement to this subject and every police-constable is expected to obtain a certificate of competency It appears, however, that at Cardiff, although classes have been held yet no distinct corps has been formed and the ambulance arrangements in connexion with the Royal Agricultural Show to be held in June at Cardiff have therefore been entrusted to 50 men from the Bristol corps

The Prevention of Tuberculosis

A largely attended meeting was held at the Weston-super-Mare Assembly Rooms on May 21st, under the auspices of the National Association for the Prevention of Consumption and other Forms of Tuberculosis. The Rev. Prebendary de Salis, rector of Weston, presided, and was supported by the majority of the members of the medical profession in the town and several others, including Colonel Bramble, Captain Phelp, and Mr. J. Cook Interesting addresses were delivered by Dr Lionel A. Weatherly (Bath) and Dr H S Ballance (the local honorary secretary) A resolution was unanimously passed recognising the urgent need of a sanatorium for the poorer classes of sufferers from consumption in Gloucester, Somerset, and Wilts, and promising to help forward the scheme by assisting to raise the necessary funds

Society for the Prevention of Cruelty to Children

The annual meeting of the Bristol and District branch of this society was held on May 21st The report stated that 553 complaints of cruelty to children had been investigated; this number was 107 in excess of those for the previous year, the increase being chiefly due to cases of indecent assault, neglect, or starvation Of the 553 cases 13 were not well founded, in 422 warnings only were issued, in 109 prosecutions were instituted (103 convictions being obtained), and nine were otherwise dealt with The financial statement was satisfactory

May 27th

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Plague in Scotland.

THE Local Government Board of Scotland have just issued a memorandum with respect to plague in which it is stated that, in view of the possibility of the introduction of plague into Scotland, the Board will assist in the identification of the disease In suspicious cases on board ship or in the earliest suspected case or cases newly developing in any district the Board have arranged for bacteriological testing, without cost to the local authority, of material from such cases This material can be received only from the medical officer of health With the memorandum are sent directions for obtaining and forwarding for bacteriological examination material from suspected plague cases which have been drawn up with the assistance of the Council of the Royal College of Physicians of Edinburgh The opportunity is also taken in the memorandum of reminding medical officers of health of the peculiar facility given for the importation and dissemination of plague by the circumstance that it affects the lower animals and most especially rats, mice, and by natural sequence cats, and of the inquiries which ought therefore to be made as to evidences of diseases among those animals on board ship and the special importance of measures for their extermination

Glasgow University

The programme of the arrangements in connexion with the celebration of the four-hundred and-fiftieth anniversary of the founding of Glasgow University is fairly well completed and the official proceedings are now practically fixed. On June 12th the ceremonies will be inaugurated by a commemoration service in the Cathedral and in the afternoon of the same day the Right Hon. the Earl of Stair, K T, the Chancellor, and Principal Storey, the Vice-Chancellor, will hold a reception in the Bute Hall, when the various delegates will be introduced and numerous congratulatory addresses will be presented; the evening will be occupied by the students' gaudeamus and by an "at home" in Queen Margaret College. The forenoon of the 13th is set apart for two orations on famous men formerly connected with the University—the one on James Watt, who did some of his most important work at the old college, by Lord Kelvin, and the other on Adam Smith, who was for a period of 15 years a professor in the University, by Professor William Smart, who is the first occupant of the chair of political economy. Following these orations there will be a graduation ceremony at which numerous honorary degrees will be conferred. On the afternoon of the 13th the new botanical laboratories will be opened by Sir Joseph Hooker, F R S, and there will be a garden party in the grounds of Queen Margaret College; in the evening a conversazione will be held in the University buildings at which some 2000 guests are expected The last day of the ceremonies, June 14th, includes an oration by Professor John Young, M D, on William Hunter, the founder of the Hunterian museum, a reception of the delegates in the art galleries and exhibition grounds, and in the evening a banquet given by the corporation and a students' ball at the University For the convenience of delegates and guests several excursions on the Firth of Clyde have been arranged for the day after the close of the official ceremonies A sketch of the history of the University has been prepared by Mr Coutts, the assistant clerk of Senate, and, as already announced, "The Book of the Jubilee" has been published.

by the Students' Celebration Committee. To this Lord Rosebery, as Lord Rector, contributes "A Foreword"; Principal Storey writes on "The Relation of Civic to Academic Life"; and Mr. Andrew Lang, as an old Glasgow student, contributes an article on "Glasgow in 1864." The poetry includes an ode in Greek by Sir Richard Jebb and an English ode by Sir Lewis Morris. The volume will form a welcome memento of a most interesting academic anniversary.

Glasgow Southern Medical Society.

At a recent meeting of this society it was resolved to send to the General Medical Council a formal statement of facts bearing on the practice of keeping open surgeries for the sale of drugs by medical men; to represent to the Council that this practice is distinctly conserved by the Pharmacy Amendment Act of 1869, and is in no way a breach of the law; and to urge that if an unqualified pharmaceutical assistant engaged in such a surgery and acting in opposition to his employer's instructions sells a scheduled poison this does not involve any illegal action on the part of the proprietor of the surgery. A petition defining the society's position in relation to the question at issue was read and approved.[1]

Glasgow Special Hospitals.

The annual meeting of the Glasgow Ear Hospital was held on May 24th. The medical report revealed a steady increase in the scope and usefulness of the institution. It is gratifying to observe that this increase extends not only to the number of the patients, but also to the clinical instruction given at the hospital. The students in attendance during the year numbered nearly 50 and as the patients' roll is close upon 1700 it is manifest that there are abundant opportunities for practical clinical study. It is proposed to enlarge the hospital by the acquisition of the adjoining property. The Hospital for Skin Diseases has also issued a satisfactory report. The new out-patients during the year numbered 1510 and the in-patients 109. The clinical classes were attended by 72 students and the resources of the hospital are also available for post-graduation study. The Duke of Montrose has consented to become patron of the hospital in succession to the late Duke of Argyll.

Glasgow Small-pox Epidemic.

The favourable reports which continue to be issued show that the outbreak is now practically at an end. A new case is an exceptional event and the number in hospital has fallen to 45. At a meeting of the town council on May 27th the minutes of the Health Committee contained a recommendation, based on the authority of the medical officer of health, that a new small-pox hospital should be erected and that the committee should be authorised to visit and to inspect sites suitable for this purpose. After some discussion this was approved. Some time ago a committee was appointed to consider the question of the re-organisation of the Health Department which, unless rumour is gravely at fault, has not for many months been altogether a happy family. It appears, however, that in consequence of the numerous engagements of the Lord Provost the committee has not yet been called together. An early meeting is now promised.

Tribute to a Paisley Practitioner.

Colonel Sir Thomas Glen-Coats, Bart., commanding the 2nd Volunteer Battalion Argyll and Sutherland Highlanders, has received the following letter from the front:—

> Camp, near Vryheid, Transvaal, April 8, 1901.
>
> SIR,—I trust you will excuse my writing to you, but I would like to bring to your notice the excellent work done by Dr. H. C. Donald, of Gauze-street, Paisley, while out in South Africa. He joined my regiment as its medical officer in the beginning of April, 1900, and only left it in the end of November, when he had his leg broken by a horse kicking him During that time he gained the complete confidence of all his comrades, both officers and men, by his care and his kindness to all our sick and wounded. He shared all our hardships, discomforts, and dangers with us, going into every fight with the regiment which we were engaged in. Not being a professional soldier, it is rather hard to mark one's appreciation of all he did for us in any public way, so I write to you, as commanding officer of his Volunteer battalion, to draw your attention to his good work and let you know how much we all appreciated it, as I feel sure you will be pleased to know of the good work of one of your officers. If you could do anything in the way of promotion for Dr. Donald I am confident of his deserving it fully and all his former comrades in South Africa would be very glad.
>
> I am, Sir, yours faithfully,
> H. P. GOUGH,
> Major Commanding Gough's Regiment Mounted Infantry.

May 28th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Cullen Case.

THE case of Mr. J. J. Cullen, the dispensary medical officer for the Castleknock district, including the prolonged legal conflict between the Local Government Board of Ireland and the guardians of the North Dublin Union, has now reached what promises to be its penultimate phase. At a meeting of the guardians held on May 22nd the chairman disclosed the result of an interview which took place recently between a deputation of the guardians and the Local Government Board in reference to Mr. Cullen. The terms agreed upon were that Mr. Cullen should resign and that no salary should be paid to him for the 12 months intervening between the issue of the sealed order and the present time; that a locum-tenent should be appointed for one month; and that an election of a medical officer should take place at the end of that period, the Local Government Board agreeing to sanction the appointment of Mr. Cullen if he should again be elected. A motion approving of these terms was adopted by 25 votes to seven.

The Death-rates of Dublin and Belfast.

Sir Charles Cameron has recently addressed an interesting letter to the Dublin daily papers in which he calls attention to the results of the census just published, which show that the population of Dublin was considerably under estimated, while that of Belfast was over-estimated. The recent death rates, being calculated on those assumed populations, showed Dublin in a more unfavourable, and Belfast in a more favourable, light than would have been the case were the actual numbers of the population known. Sir Charles Cameron observes that as Belfast has no township and corresponds practically to the Dublin metropolitan area the population of the latter still exceeds that of the former by 25,935.

Royal College of Surgeons in Ireland.

No less than 10 new candidates have offered themselves for election on the Council of the Royal College of Surgeons in Ireland at the ballot which will take place on June 3rd

Cottage Hospital for Larne.

Mr. Hugh H. Smiley of Larne has handed over to trustees the sum of £5000 to build and to endow a cottage hospital for Larne. These trustees have the entire responsibility of selecting a site, erecting the building, and arranging details as to management and terms of admission.

The Midwife Question at Caledon.

Dr. C. J. Clibborn (Local Government Board medical inspector) held a sworn inquiry at the Court-house, Caledon, co. Tyrone, last week in reference to the death of a woman at Cronghill, Caledon, on March 30th last, on whose body an inquest was held, when the jury found that "they attached no blame to the midwife, who had done all she could for the deceased according to her knowledge, and unanimously condemned Dr. Patterson for neglect of duty." A public meeting was held in Caledon to protest against the verdict and the Local Government Board of Ireland was requested to hold an inquiry. From the evidence it appeared that the husband of the deceased came for the medical man, Mr. R. D. Patterson, on March 29th, and although he had no "line" the medical man walked a mile to see the woman. On arrival he found only a little girl, 10 years of age, with the woman who was in an office house, made temporarily habitable, and with no fire. She was suffering from puerperal septicæmia and was in a dying condition, with a temperature of 102°F. and a pulse-rate of 120. The entire surroundings were filthy and the woman's clothes had not been changed nor had she been cleaned. The medical man said to the husband that his wife's condition was hopeless and that he would hold them all responsible. He gave medicines to ease the poor woman's pain. The midwife admitted that she had not changed any of the clothes from the date of the confinement (March 24th) until the death of the woman on the 30th. When asked why a medical man was not sent for sooner she said that that was for the friends to do, not for her.' She admitted that there was singing and drinking in the house on the night of the birth and on the following night. The husband said that he had left all to the woman who had attended his wife. It would appear also that the priest had been sent for to administer the last rites of the Church before the medical man was sent for. The decision of the Local Government Board will be given after some time

---

[1] The text of the petition is published on page 1543.

The Water-supply of Belfast.

Owing to the long-continued dry weather the reservoirs are down five feet six inches below the high water level The water commissioners, with the view of obtaining a temporary supply of water from the new Mourne scheme, have ordered the construction of a short temporary diversion channel in the Annalong valley to divert the water of the river into the pipes connected with the main conduit, as it will be impossible to have the permanent weir and other works completed in time to afford any relief during the present season. This temporary arrangement will be effected in a few weeks.

The Royal University Commission.

The report prevalent in Ireland for some time that the Government were finding great difficulties in the selection of men willing to act on the Royal University Commission has been confirmed by the statement which was made by Mr. A. J. Balfour in the House of Commons on May 24th, in reply to an inquiry by Mr. T. Healy, M P. Mr. Balfour was unable to give the names of the Commissioners. One of the reasons for the delay, he said, was the large number of Commissioners—Englishmen and Scotsmen—who have been asked to serve People engaged in education could not take evidence in Ireland after the beginning of an academic term. Another delay arises from the circumstance that an invitation is sent to a gentleman and he finds that he is not able to attend and then the invitation is sent to someone else. In these circumstances, said Mr. Balfour, delays are inevitable. The truth seems to be that the question is such a thorny one that few care to accept the position of Commissioner, as no matter what recommendations may be made as the result of the sittings of the Commission the most adverse criticism will come from one or other quarter in Ireland.

The Removal of Lunatics.

Mr. E S Finnegan, the coroner for the city of Belfast, appeared before the Poor law guardians of that city on May 21st, and having given illustrations of the present barbarous plan of removing lunatics suggested for their approval the following method Suppose a person was noticed to be of unsound mind, a relative or friend could go to the relieving officer of the district who would fill in a form provided for the purpose and direct the friend to get a medical man (if he could pay his fee, or, if not, a dispensary medical officer) to meet at the lunatic's house at some specified time. If the medical man, after examination, was satisfied that insanity existed a magistrate was to be found and brought to the house. A legal court would then be formed and the medical man in the presence of the magistrate, could sign the certificate in the proscribed form. The magistrate would then sign his certificate for the transfer of the patient, not to the workhouse but to the district lunatic asylum The patient was then to be taken to the asylum by a friend in a cab, and the resident medical superintendent had told him (the coroner) that he would admit every patient in whose case the various steps in the plan he had suggested had been carried out The coroner was thanked for his remarks It would appear that there are two methods by which patients in Ireland are admitted to public asylums. The friends finding a relative insane go to the asylum and procure a "house" form and get a medical man to fill it up But to do this he must state certain symptoms of insanity that he has personally noticed. In the case of dispensary patients, to save time and any risk of being blamed, the dispensary medical officer often sends the patient to the workhouse as a kind of half-way house, where there is plenty of time to investigate fully the question of insanity, and afterwards the patient can be transferred to the asylum. But there is another method—a most barbarous plan—by which, it is said, three fourths of the lunatics in Ireland are committed. Suppose a man shows signs of being a "dangerous lunatic," a relative makes a sworn information that he proposed to commit "an indictable crime" The police, acting on this affidavit, arrest the lunatic (often he is handcuffed, sometimes tied on a car) and drive him to a petty sessions or police-court, where before two magistrates he is charged and committed as a common criminal with the stamp of a criminal on him for all time, even if he recovers The magistrates then give an order for his admission to the nearest asylum. It is reported that neither in Great Britain nor in any other country do such an absurdly cruel and barbarous law and system prevail, and it is to replace this method that the Belfast coroner has suggested an alternative and more humane scheme.

Down District Asylum.

Mr. M. J Nolan, the resident medical superintendent, in his annual report, records that 500 cases were under his charge in the year ended Dec. 31st, 1900, for physical ailments, which gives a fair idea of the extent to which bodily disease is associated with mental disorder. A large proportion of the cases came from workhouses, often only when the decay and degradation of years required all the resources of an asylum In the meantime the entire burden of their cost of maintenance has been thrown on the union districts and the country at large has been deprived of the Treasury contribution of 4*s.* per week per head, since for want of due certification as lunatics they were denied the advantages of legal recognition. Recent legislation was provided for such long delayed recognition by the proposed establishment of auxiliary asylums, either as separate establishments or as departments of existing asylums, but the grant in such cases will be but 2*s.* per week per head. It is difficult to see why such a reduction should be made, as surely it is very often patients of this class who so largely tax the nursing staff and equipment of the asylum hospitals. There is something anomalous in the legislative philanthropy which doles out to the chronic harmless lunatic but a moiety of the State support granted to his more fortunate but dangerous brother.

May 28th

PARIS.

(FROM OUR OWN CORRESPONDENT.

Election of Dr. Laveran to the French Institute.

AT the Institute (Academy of Sciences) the election of a member in the section of medicine to succeed the late Professor Potain took place on May 20th. This election has given rise to very active wire-pulling in medical circles. The candidates were numerous and all of them were distinguished, the list being M Charles Richet, M. Cornil, M. Laveran, M. Jaccoud, M Lancereaux, M. Fournier, and M. Charrin. M. Charrin was chiefly supported by M. Bouchard, who is all powerful in the Section of Medicine in the Academy of Sciences; he was, in fact, placed first on the list which the section draws up in accordance with custom before the whole Academy proceeds to vote. M. Richet had the support of the old friends of his late father who was a member of the Institute. M. Laveran was supported by the members and friends of the Pasteur Institute; he came out at the head of the poll in the third voting after a very animated contest. M Laveran discovered the hæmatozoon of malaria, and his name has so often figured in the pages of THE LANCET that it would be superfluous to give details of his career It may be mentioned, however, that the greater part of his life has been spent as an army surgeon, and that notwithstanding his success as a *savant*—for he was professor at the École de Santé Militaire du Val de Grâce and a Member of the Academy of Medicine—his rise in military rank was surrounded with difficulties on account of the jealousy of his official superiors On his becoming a Member of the Academy of Medicine he was ordered to leave Paris and was appointed medical officer of the hospital in Lille He thereupon resigned his position in the army and quitted the service to join the Pasteur Institute.

"*Kleptomania*"

A Paris medical man practising as a specialist in mental diseases has just been the victim of a heartless trick which is not without its humorous side. One day he was consulted by a man of very distinguished appearance and giving a very aristocratic name, who said: "Doctor, I have come to ask you to cure my daughter of a terrible affliction She is a kleptomaniac and because of this we are heart-broken. I have brought her with me and she is here in the next room" The girl was then shown in and the medical man commenced treatment by means of suggestion which required several attendances. From the first, under the influence of her hysterical mania she every time carried away from the practitioner's consulting-room some small object which the father sent back next morning. The medical man ordered his servants not to pay attention to these eccentricities of the patient who, it was thought, would soon be cured, but one day she carried off a jewel-box of great value taken from an adjoining room into which she had been shown. The owner was not anxious at first, but the missing article was not returned the next day as the others had been, and the girl never came back. At last he sent to the address given by the aristocratic personage and then found that the address was false, and that he had been victimised by two rogues of exceptional craftiness.

A Proposed Leper Asylum.

At the meeting of the Academy of Medicine held on May 21st M. Besnier read a report on the proposal to establish a sanatorium for lepers in the commune of Ronceux (Vosges). This proposal, originated by M. Santon, has given rise to much opposition in the neighbourhood and the Academy had been requested by the Conseil d'État to advise upon the question. Provided, said the report, that sufficient hygienic precautions are taken, the risk of the spread of leprosy is far from being so great as seems to be supposed. Some of the Paris hospitals—the Hôpital St. Louis for instance—contain lepers, but extension of the disease has never been observed. There still are in France a few foci of leprosy not quite extinct; if a leper asylum were founded it ought to be in the neighbourhood of these foci of leprosy—on the Mediterranean coast for instance. From the humanitarian point of view it would be very useful; a leper asylum would render great services to patients who had contracted leprosy abroad. It ought to be a free sanatorium. A leper asylum does not form a danger to the neighbourhood, since if sufficient precautions are taken there is hardly any prospect of the disease spreading. Foreign authorities on leprosy do not think that the dangers of contagion are very formidable. Hansen states that at Bergen in Norway lepers move about freely beyond the limits of the asylum without extending the disease. At Christiania, a part of the country where leprosy rages, the disease does not occur in the vicinity of the leper asylums The sanatorium established in Prussia has not given rise to any inconvenience. Dr. Ehlers of Copenhagen is of opinion that leper asylums may disseminate the disease to some extent; they ought, therefore, not to be placed in districts free from leprosy. César Buuck also thinks that a leper asylum may be a source of danger. The committee advised the Academy to reply as follows to the questions put by the Minister of the Interior: 1. Under the conditions and with the reservations detailed in the report the Academy is of opinion that if placed as near as possible to a region where some lepers still exist a sanatorium for lepers would be of great utility. 2 Under the conditions and with the reservations aforesaid, if in a well-chosen and isolated situation, worked under strict regulations laid down by the sanitary authority and subjected to constant and effective supervision by the sanitary authority both within and without, a leper asylum ought not in the present state of knowledge to be a source of danger to the public health. 3 As the present state of the law in France does not render this supervision possible a committee nominated by the Academy would decide on the measures which ought to be taken in this respect. The conclusions arrived at in M. Besnier's report will be discussed at the next meeting of the Academy.

May 27th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Vegetarianism.

IN the Berlin Medical Society a lengthy debate arose lately on a paper read by Dr. Albu on Vegetarianism. He said that it must be ascertained (1) whether a person was able to live on a purely vegetarian diet and (2) whether this diet was advisable As to the first question he alluded to the observations of Professor Voit and Dr. Rumpf who found by experiments on two men, aged 28 and 19 years respectively, that in both there was nitrogenous equilibrium. He had himself investigated the phenomena of metabolism in a lady living for the last six years on a strictly vegetarian diet and whose health was perfect. The research was continued over five days, the food consisting exclusively of bread, fruits, nuts, and salad, and the result was that the nitrogen assimilated during this period showed an increase An exclusively vegetarian diet was therefore a practical possibility. Dr. Albu, however, said that in his opinion this diet was not advisable for healthy persons, because vegetable albumin was not so easily absorbed as animal albumin, and because a vegetable diet was too bulky and too monotonous. For invalids a vegetarian diet might, however, sometimes be in every way advantageous, not, however, in its strictest form, but combined with milk. The conditions in which such a diet was indicated were: (1) neuroses and neurasthenia; (2) nervous diseases of the gastro intestinal canal, but only for periods of from six to eight days duration; (3) chronic constipation; (4) general obesity; (5) gout; (6) neurosis of the heart and Graves's disease; and (7) Bright's disease. Contra-indications were afforded by all diseases of the gastro-intestinal canal and cardiac failure. Some persons had a marked idiosyncrasy the effect of which was that vegetables disagreed with them. The drawbacks of vegetarianism had been exaggerated by its adversaries. Dr. Albu had never observed either gastrectasia or dyspepsia or any other undesirable symptom.—In the discussion Professor Rosenheim said that although certain persons, such as peasants accustomed to it from their youth, might live on a strictly vegetarian diet it would be a different thing suddenly to change the food of a man who had been a meat-eater all his life. In these cases he had observed that the patients felt ill, and therefore when prescribing a vegetarian diet he had always for a long time recommended the addition of butter, milk, and eggs. In neurasthenia, gastric ulcer, and carcinoma this "lacto-vegetarian" diet proved valuable.—Dr. Schonstadt made a reference to the researches of M. Hofmann and Professor Rubner, the former of whom observed general debility and the latter gastro intestinal troubles as sequelæ of vegetarian diet. Vegetable albumin was of course not easily absorbed. To get the necessary daily amount of albumin from bread not less than 1740 grammes must be eaten. He mentioned that in the beginning of last century prisoners received an exclusively vegetarian diet, the result being an enormous morbidity and mortality, but as soon as mixed food was given the state of health in the prisons became normal. It was a mistake to suppose that there were nations which lived on an exclusively vegetarian diet, for they all took some animal food in addition to articles of vegetable origin.—Professor Fürbringer was of opinion that the instances in which vegetarians had beaten the record in athletic performances must be regarded as exceptions. He had never prescribed a strictly vegetarian, but always a lacto-vegetarian, diet, especially in sexual neurasthenia when too much animal food had been previously taken. In Bright's disease and in general obesity this diet was advisable; in gout, however, its utility was still doubtful. The human species belonged neither to the carnivora nor to the herbivora but to the omnivora.—Dr. Arthur Meyer said that he had lived as a vegetarian for a fortnight *experimenti causa* and his weight increased by 1 5 kilogrammes (three pounds and a quarter) during that time.—Dr. Hauchecorne gave interesting details with regard to vegetable-feeders among the lower animals He said that there were but few herbivorous animals, the majority being omnivorous. It was erroneous to suppose that for the lower animals flesh was the most suitable food in hot climates and vegetable products in cold climates. Herbivorous animals were, as a rule, not so intelligent as the carnivorous and the assertion that they were naturally of a quiet disposition was a mere fable —Dr. Albu, in replying, recommended the lacto-vegetarian diet for certain diseases

ROME.

(FROM OUR OWN CORRESPONDENT.)

Diversion of Blood from the Portal Circulation by Surgical Means.

AT a recent meeting of the Medico-Chirurgical Society of Bologna Professor Schiassi reported three cases in which he had diverted blood from the portal into the general circulation in order to relieve hepatic engorgement and the ascites dependent upon it The operation consisted in grafting the omentum or mesentery between the peritoneum and the abdominal muscles so as to establish anastomotic communication between their respective vessels. By this means excessive intravenous pressure in the portal system is relieved and it is thought also that a smaller amount of noxious matter finds its way to an over worked liver. Surgical interference Professor Schiassi considers to be indicated (1) in cases of passive hepatic congestion when ascites is beginning, (2) in cases of capsular cirrhosis before the growth of connective tissue has involved and damaged the liver cells; (3) in portal phlebitis; and possibly (4) in certain forms of biliary cirrhosis In each of Professor Schiassi's three cases there was cirrhosis with ascites, and the result of the operation was immediately successful, except in one case where a second grafting was required to supplement the first

Anti-malaria Campaign

The Italian Red Cross Society have succeeded in collecting by voluntary subscription the greater part of the sum necessary for renewing the summer campaign against malaria in the Agro Romano Some 5000 lire are still needed to make the scheme practicable, and an appeal for funds is being made to the Government by the society and others interested in the undertaking

The Use of Glycerine in the Preservation of Vaccine Virus

In the report of THE LANCET Commission on Glycerinated Calf Vaccine Lymph[1] it was stated that the discovery of the value of glycerine for the preservation of vaccine virus was due to Copeman, Chambon, and Saint Yves Menard According to Rossi Doria[2] this honour belongs to Professor Leoni, formerly director of the Vaccine Institute of Rome, who was the first to demonstrate that vaccine virus in the fresh state is contaminated by germs, among the most important of which are those of pus, and that these germs disappear in the lymph when it has been preserved in glycerine for a time—from three to four weeks—under certain conditions of temperature It is stated that the experiments determining this important fact were made by Leoni in 1889 and were published by him in the *Rivista d'Igiene e Sanità Pubblica*, and that Copeman's work dated from 1892 and that of Chambon and Saint Yves Menard from 1893

Congress of "Medici Condotti"

The second congress of "Medici Condotti" (district doctors) was held in Rome on May 5 h and the three succeeding days for the purpose of agitating for reforms in the conditions under which that hard working but ill paid class of medical men are now discharging their onerous duties It is two years since the first congress of the same kind sat at Como, and little or nothing has as yet been done towards ameliorating or removing their many grievances Of these there are especially two about which the loudest complaints are made—viz, the insecurity in the tenure of the office of the "medico condotto," and the power possessed by the communal councils of cutting down his salary at their discretion Resolutions were passed to the effect that after the lapse of the three years of probation prescribed by law for the newly appointed candidate he should be secure in his post, and that during the period of probation as well as afterwards the communal councils should not have the right of dismissing him except for some sufficient cause and with the consent of the Provincial Sanitary Council Further, the salary of the "*medico condotto*," once fixed, should not be subject to reduction It was also resolved that a month's vacation ought to be granted to him yearly, that a reduction should be allowed in his railway fares, and that after 25 years' service a pension should be granted to him without its being required that he should resign his appointment

The Controversy between Professor Grassi and Major Ronald Ross

The last issue of the Policlinico[3] contains the close of the polemic between Major Ross and Professor Grassi on the question of priority in the discovery of the extra-corporeal life cycle of the malarial parasite The controversy would appear to hinge upon a doubt as to whether or not a general statement admittedly made by Major Ross in the preface to the paper in which he first announced his success in cultivating malarial crescents in the mosquito applied to the particular insects in which he first observed the development of the pigmented bodies to take place To any impartial reader it will not appear in the least doubtful that the two specimens upon the fate of which so much scientific progress was to depend were really reared from the larvæ by Major Ross and had never been given the chance of disqualifying themselves for experimental purposes by indiscriminate draughts of forbidden blood Professor Grassi, however, insists that a special statement to this effect should have been made by Major Ross, and he takes advantage of an admission by the latter in a private letter to Dr. Charles to show that Major Ross himself is of the same opinion! But the criticism, even if it were justified by Major Ross's inadvertence, is a carping and unworthy one at this time of day when subsequent investigations have made it so clear that the bodies observed by him had without question the origin and nature which he claimed for them Fortunately for the discoverer no criticism can now rob him of the well-earned distinction of having been the first to find the road to the solution of the problem, although many, including Professor Grassi himself, may share with him the honour of supplementing and completing it

May 24th

NEW YORK.

(FROM OUR OWN CORRESPONDENT)

Withdrawal of the Anti Christian Science Bill.

THE Bell Bill which was drawn up and introduced into the State Legislature of New York for the purpose of placing Christian Scientists, osteopaths, and others who might be practising the healing art without being legally qualified to do so under the same restrictions as all who desire to follow the medical profession in New York State was overwhelmed by an avalanche of amendments which would have rendered its action as intended by its original promoters abortive. The Bill was consequently withdrawn, which under the circumstances was the best thing that could have happened. The amendments were found to be necessary for the passage of the measure on account of the strong opposition brought against it in its original form The result of this failure to restrain the quack element in New York State has proved beyond doubt that public sentiment is not favourable to restrictive Medical Acts and the numerous hearings given to the Bill, coupled with the sensational newspaper reports, have certainly helped, rather than hurt, the cause of the Christian Scientists and other divisions of what may be termed the illegitimate medical fraternity. The controversy over the Bill has raised in the minds of members of the legitimate medical profession grave doubts as to whether it is wise to control Christian Scientists and the rest by legal means Agitation seems to strengthen their position, they are regarded somewhat in the light of martyrs and medical men are esteemed as would be persecutors Another reason perhaps the most potent and one which has not been mentioned in American journals, is that the Christian Scientists owe much of their wide-spread influence to women, and women are a mighty power in the United States Possibly the course dictated by the soundest common sense would be to ignore these fads, except when their professors and followers contravene the law in a too flagrant manner.

Isolation of Consumptive Convicts in Texas

Texas, which is usually looked upon as one of the most backward States in the Union as regards matters pertaining to advanced civilisation, has recently made a forward movement which should put to shame many of those States which claim to be in the front rank of progress The treatment of convicts in various parts of the United States has long been the subject of adverse criticism, and the custom of allowing criminals afflicted with tuberculosis to mix freely with, and even to sleep in the same compartments as, healthy prisoners has been frequently denounced in medical journals in this country The fact that Texas has isolated its consumptive convicts is not generally known, but the authorities have even gone further than this, for its sick convicts receive practically the same treatment as that followed in the ordinary sanatoria for consumptives. They are fed on nourishing food and are given stimulants when necessary Cleanliness and sanitary precautions are strictly enforced If not confined to bed the men are required to live entirely in the open air and to sleep in a large stockade where, it is needless to remark, each enjoys an ample sufficiency of pure air. Each one works according to his strength and the employment is wholly restricted to market gardening; nevertheless, this isolated convict settlement has returned to the State in two years a net profit of about $2500 (£500). The example set by Texas is one to be copied.

Care of the Foundlings in New York.

The New York County Visiting Committee of the State Charities Aid Association have just issued their annual report dealing with the conduct of the various charitable institutions under their supervision. The most satisfactory item of news in this publication is that showing the improved methods now in force for the rearing of foundling infants. Only a few years ago the management of the Infants' Hospital on Randall's Island was a public scandal. The report published by the committee in December, 1897, stated that of 366 infants under the age of six months admitted to the hospital during the year 1896 only 12 were alive on April 15th, 1897—a death-rate of $96\frac{7}{10}$ per cent. This condition of affairs aroused public indignation and sentiment, and philanthropists came forward with money and plans to endeavour to devise methods whereby these unfortunate infants might have a fair chance to live. The fact was recognised that so long as the infants were massed together in one building and fed to a great extent by artificial means the mortality amongst them must necessarily be very large. The State Charities Aid Association then suggested that the foundlings should be removed as soon as possible after their reception at the Infants' Hospital to carefully selected families in the country, and that when the children became healthy and strong homes should be provided for them by adoption. This placing out system has been practised successfully for a considerable time in Massachusetts and Pennsylvania. The Association for Improving the Condition of the Poor joined with the State Charities Aid Association in this Samaritan endeavour and the joint committee approached the Commissioner of Charities for the boroughs of Manhattan and the Bronx with a proposal offering to transfer a certain proportion of the foundlings to boarding-houses in the country. The Commissioner gladly welcomed the offer, stipulating that the committee were to meet all expenses and that the number under their care should not exceed 25 at any one time. The work was begun in April, 1898, and the results have been most encouraging, the mortality-rate having fallen from 55·9 per cent. in 1899 to 18·9 per cent. in the year ending March, 1901. The committee have also been equally successful in providing permanent homes for the children by adoption. Other public authorities in Greater New York were so impressed by the success of the experiment that the Commissioner of Public Charities for the boroughs of Brooklyn and Queens in 1900 requested the committee to perform the same service for the foundlings coming under his charge. This request was granted under certain conditions. In December, 1900, the Commissioner for Manhattan and the Bronx, finding that the system had more than realised the expectations of its promoters, asked the committee to take charge of all foundlings coming under his care who had been baptized in the Protestant faith, having up to that time limited the number to 25. The Roman Catholics have now formed a guild—the Guild of the Infant Saviour—and they will follow the plan pursued with such beneficial results by the Protestants. Both agencies will receive the foundlings directly from Bellevue Hospital, to which institution they are first taken, thus obviating the transfer from Bellevue to the Infants' Hospital and thence to the country, except in instances in which special medical treatment in the hospital is desirable. It may be said that the foundlings who since January have been taken directly to the country are all alive at present. The fact has been demonstrated so thoroughly and with such frightful effects that many foundling hospitals, however carefully managed, are nothing more or less than death-traps for infants, that it is to be sincerely hoped that the example of New York may be widely followed and that the wholesale "massacre of the innocents" may thus be stayed.

Sanatorium for Indigent Women and Children Suffering from Tuberculosis in New York State.

The method of treating consumption, especially in its incipient stages, by allowing its victims plenty of fresh air and wholesome food has been shown to be the only effective and rational means of checking the spread of the disease. In every civilised country of the world sanatoria for those suffering from tuberculosis are springing up on all sides. There is, however, a class of people who, though living under conditions peculiarly favourable to contracting and disseminating the malady, are by reason of their poverty unable to escape these conditions. The class referred to comprises working girls and poor young married women and children suffering from tuberculosis. A pressing need of the times is the establishment of sanatoria for such as these. It must be ever borne in mind that not only should the consumptive poor be treated for their own sakes and upon general charitable principles, but also as a precaution against spreading contagion. Tuberculosis will never be stamped out while means of contracting and propagating the malady exist as they do at present amongst the poor. Recognising this truth in New York a committee of women has been formed for the purpose of founding an institution for the class referred to above, and the project has prospered beyond the best hopes of its founders. It is now three months since the organisation was formed and already more than $30,000 (£6000) have been subscribed. The work, however, cannot be begun in a practical manner until $100,000 (£20,000) have been obtained, and this sum must be forthcoming by June 1st if arrangements are to be made this summer to receive patients. Tuberculosis is very prevalent in New York State and there was an increase in 1899 of 300 deaths from the disease over the year preceding. In 1900 10,000 cases were reported to the New York Medical Board of Health and it is estimated that there are at the present time in New York City alone 30,000 cases. The proposed sanatorium at Stony Wolde will be non-sectarian and the medical board under whose control it will be managed is composed of physicians of the highest standing in New York and Albany. Among the members of the committee is Mrs. George H. Shrady, the wife of the editor of the *Medical Record.*

May 22nd.

Obituary.

JOHN DAVID WILLIAMS, M.D., C.M., B.Sc. (PUB. H.) EDIN.

THE death of Dr. J. D. Williams is pathetic in the extreme. By sheer hard work and by his scrupulous attention to matters of detail he had managed to secure the confidence of the general practitioners within a considerable distance of Cardiff and although still under 40 years of age he had established for himself a reputation as an operator and accurate diagnostician which many older men might well have envied. Born in the Isle of Anglesey in the year 1864 he became at the age of 16 years the pupil of Dr. Griffith R Griffith of Carnarvon. At 18 years of age he entered the University of Edinburgh and graduated M.B. and C.M. in 1888, obtaining the Freeland Barbour scholarship. For a short time he was demonstrator of anatomy at the Edinburgh School of Medicine. In 1892 he took the public health degree of B Sc. and for a time his inclination turned to the special science of preventive medicine, but his tastes were evidently in the direction of gynæcology, for in 1890 he was awarded the University gold medal for his M.D. thesis upon the pathology of the female generative organs. After leaving Edinburgh he was in practice for three years at Dowlais, near Merthyr, but his health broke down and he went to Cardiff with the intention of devoting himself exclusively to gynæcological work. His first public appointment was in 1896 upon the consulting staff of the Cottage Hospital which had just been established by the exertions of Mr. Henry Naunton Davies at Porth. In the following year he was elected upon the staff of the Cardiff Provident Dispensary and of the Cardiff Infirmary, a special ward being allotted him at the latter institution, though, unfortunately, through lack of funds, the original number of beds have latterly been sadly lessened. As evidence not only of the need for this special department but of the success which has attended Dr. Williams's labours it is sufficient to say that more than 60 patients are at the present time awaiting admission to the gynæcological ward of the infirmary. He was an enthusiastic Freemason and in 1896 was one of the founders of the Prince Llewellyn Lodge at Cardiff. At the time of his death he was junior warden of the lodge and but for his illness would have been invested senior warden and next year would doubtless have occupied the chair. The history of his fatal illness is unhappily but a repetition of that of many others. At Easter he visited Rome and, though usually peculiarly careful in such matters, he drank some water from a well near the city and soon after returning to Cardiff he developed typhoid fever. Although apparently doing well on May 17th hæmorrhage occurred and he died on the morning of the 21st. He was buried on the 24th in the picturesque churchyard of the village of St Fagan's, the seat of Lord Windsor, the funeral being attended by practically every member of the medical profession in Cardiff and by many from the surrounding district. Never before was there such a gathering of Cardiff practitioners. Many of the brethren from the Prince Llewellyn Lodge and other lodges were also present. Of Dr. Williams's personality it is difficult to speak in terms that will not seem exaggerated. Although exceptionally quiet and undemonstrative he had the faculty of securing the confidence both of the colleague to whose assistance he was called and of the patient for whose welfare they were jointly solicitous. Outside his profession he had a charm peculiarly his own, and the social life of Cardiff has sustained through his untimely death a very grievous loss.

Medical News.

UNIVERSITY OF CAMBRIDGE.—The following egrees in Medicine and Surgery were conferred on ay 23rd:—

Master of Surgery—W. D Harmer, King's.
Bachelor of Medicine—H. Edmondson, Clare, K. E Crompton, Caius; and A B. Taylor, Downing.
Bachelor of Surgery—A. R. M. Brenan, Trinity; K. E. Crompton, Caius; and A. B. Taylor, Downing.

. sum of £21,500 from the Benefaction Fund has been ppropriated to the erection of the new Medical School uildings, including the Humphry Museum.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—'ELLOWSHIP EXAMINATION.—The following candidates aving passed the necessary examination have been admitted 'ellows of the College:—

Mr A. G Beale, Mr. M. F. Cahill, Mr. E. P Frazer, Miss G. H. Giffen, Mr E. J. A. Haynes, Mr. R. M. Hugo, Mr. J. J. H. Jackman, Captain S. J. C Prittie-Perry, Mr W. Smartt, Mr. A. W. Tabuteau, Mr. G T. Whyte, and Mr R. B. Wright.

'he following candidates have passed the primary part of he Fellowship examination:—

Mr. A. E Boyd, Mr R. W. Burkitt, Mr. K. Fleury, Mr. J. J. McConnell, and Mr. S. S. Pringle

THE SOUTH AFRICAN CIVIL SURGEONS' DINNER.—We are asked to announce that at the dinner which is to be held at the Hotel Cecil next Wednesday, June 5th, at 7 30 for 8 P.M., a few seats will be reserved for those who have been unable to notify their intention of attending. Tickets will be paid for on the stairs. No seats will be reserved beforehand except those at the high table, but seats may be retained on arrival by filling in the blank card to be found in each place. Applications have already been received for over 130 dinner tickets.

THE ASSOCIATION OF ASYLUM WORKERS.—Sir J. Crichton-Browne presided on May 24th at the annual meeting of the members of the Association of Asylum Workers in the rooms of the Medical Society, Chandos-street, W. The chairman stated that there was a slight diminution in the number of members (from 3006 to 2868), due to the absence of Army reservists serving their country in South Africa. It was most satisfactory to note that the colonies were coming into line with them. With respect to the possibility of lunacy legislation he thought that having regard to the advanced stage of the session and the state of public business the prospect was sadly remote No opposed Bill would stand a chance of passing, while no measure would be approved that did not deal adequately with the pension question. Asylum workers, he said, were of a much more nervous class that they used to be, though the standard of work was higher. Their work was honestly performed, without the prospect of the Victoria Cross, a testimonial, and a dinner. It was not, however, without its compensating benefits, because while they were earning their livelihood they were doing good Christian work which proved a blessing to the inmates. Much, however, remained to be done in the diligent treatment of chronic cases, and he urged them never to regard any case as irretrievably hopeless. Dr. Robert Jones seconded the adoption of the report, which was agreed to, and on the motion of Dr. Sidney Coupland, seconded by Miss Honnor Morten, the balance-sheet was adopted. Sir J. Crichton-Browne was re-elected president for the ensuing year.

MR. JOHN DUNSTAN, M.R.C.V.S., of St. Mellion, Cornwall, has been appointed professor of surgery and materia medica at the Royal (Dick) Veterinary College, Edinburgh, vacant by the resignation of Professor Whitecross. Mr. Dunstan is a member of a Cornish family who for six generations have practised veterinary surgery and he has for several years acted as honorary secretary of the Western Counties Veterinary Medical Association.

INFANT MORTALITY IN NORTH DEVON.—An inquest was held at Ilfracombe on May 21st by the deputy coroner (Dr. E. J. Slade-King) upon an illegitimate child, aged eight weeks. The evidence showed that the mother, who had been recently discharged from the Barnstaple Workhouse, had fed the deceased upon milk, bread, and biscuits, and a verdict of "Death from improper feeding" was returned. Dr. Slade-King stated that the mortality of illegitimate children in the Barnstaple district during the past year was 50 per cent. of those under one year of age, and the medical men of Ilfracombe had therefore decided not to give certificates of death in such cases.

ROYAL MEDICAL BENEVOLENT COLLEGE.—At the annual general meeting held on Wednesday last at the office of the college in Soho square, the following candidates for pensionerships and foundation scholarships were reported by the scrutineers, Dr. Baines, Dr. Felce, and Dr. Galton, to have obtained the largest number of votes and were declared to have been duly elected:—

PENSIONERSHIPS.

1 Eliza F. Chapman ...	10,238	3 Ellen Bull	7141
2. Fanny A. Coleman ...	8713	4. Charlotte E. Davies ...	6616

FOUNDATION SCHOLARSHIPS.

1. G. A. L Anderson ...	10 939	5. G. W. Adams	6189
2. C. A. Mallam	9475	6 T. G M. Clarke ...	6168
3. A. R Hemsted	6897	7. D. A. Buchan	5427
4 W. Bourne	6644		

ANNUAL MEETING OF THE BRITISH MEDICAL TEMPERANCE ASSOCIATION.—The twenty-fifth annual meeting of this association was held at the Temperance Hospital on May 21st. In the unavoidable absence of the President, Professor G Sims Woodhead, the chair was taken by Major G. K. Poole, M.D.—The report showed an addition during the year of 28 new members and 92 new student associates, and a total of 495 members, 584 medical students, and four lay associates —Dr. T Morton, the treasurer, presented the balance sheet, showing an income of £107 but closing with an adverse balance of £26.—After the business had been concluded a paper was read by Dr. J. J. Ridge on the Temperance Question as affected by Modern Experiments. He contended that these showed that alcohol was not a true food since even though some was used up in the body its action on the various tissues showed that it was not harmless as food ought to be in any reasonable quantity. It had been proved to be deleterious even in moderate quantities by Kraepelin, Fürer, and others.—A discussion ensued in which Major Poole, Dr. S Andrews (Basingstoke), Dr. T. Rushbrooke, Mr. W. F. Hazel, and others took part, and the following motion was moved by Mr. F. Churchill, seconded by Dr. R Paramore, and carried unanimously: "That the leaders of the profession and teachers in our medical schools be requested to urge the students attending their lectures to point out hereafter to their patients the dangers of the habitual use of alcoholic liquors."—A new departure was made by agreeing to admit as subscribers any persons (whether abstainers or not) who desire to assist the association in this way to promote the cause of temperance. Subscriptions should be sent to the honorary secretary, Dr. J. J. Ridge, Enfield, Middlesex.

Parliamentary Intelligence.

HOUSE OF COMMONS.

THURSDAY, MAY 23RD.

Disease among the Troops in South Africa.

SIR WALTER FOSTER asked the Secretary of State for War if he could state the number of cases of typhoid fever and the number of deaths among the forces in South Africa during the month of April, and also the number of cases of plague and the number of deaths from that disease, up to the latest advices, among the *soldiers and others engaged* in the campaign.—Mr. BRODRICK replied: The returns for April received only take up to the 19th; there had been then 1052 admissions for enteric fever and 140 deaths. The numbers of cases of plague have, according to latest advices, been as follows—viz , 14 soldiers, 20 native drivers, and eight other employés; of seven deaths reported none are stated to have occurred among soldiers —Dr. FARQUHARSON asked the Secretary of State for War whether he could state the number of sick in the 2nd *Worcesters* at Bloemfontein between April 4th *and* 27th, 1900, what were the total of enteric fever cases, and what the ratio of mortality was up to May 31st.—Lord STANLEY replied to the question, saying: The number of sick admitted to hospital between April 4th and 27th, 1900, was 94. It is not possible to differentiate the cases of enteric fever from the information at the disposal of the War Office, but up to May 31st there were 15 deaths from enteric fever.

Treatment of Tuberculous Carcasses.

Mr. FIELD asked the President of the Local Government Board whether he was aware that the late medical officer of health of the City of London stated in his annual report to the Corporation, 1900, that he would condemn all carcasses affected by localised tuberculosis; and, in view of the statement of the Royal Commission on Tuberculosis that such meat might be eaten with impunity, and seeing that the late medical officer of health of the City of London was paid part of his salary by the *Local Government* Board, would he state what steps the Board would take.—Mr. WALTER LONG said: I am aware of the statements made on this subject by the late medical officer of health of the City of London in his report for 1899, but I am not responsible for the views which he entertained. I may add that no part of his salary was paid by the Local Government Board.

Educational Appointment for Dr. Henry Ward Irvine.

On the motion for the adjournment of the House for the Whitsuntide vacation,

Mr. MCKENNA called attention to the appointment of Dr. Henry Ward Irvine as one of His Majesty's inspectors of schools. He gave to the House an account of the proceedings before the General Medical Council when Dr. Irvine was charged with unprofessional conduct in connexion with an institution in Birmingham and the Council found the charge proved and suspended further proceedings in the case for six months, and explained that since then Dr. Irvine had withdrawn from the institution and accepted this appointment. The hon. Member submitted that Dr. Irvine should not have received the appointment whilst a charge of this kind was hanging over him. He had no wish to mention the names of the persons who were interested in this gentleman.

Mr. CHAMBERLAIN said that as the whole speech was an insinuation he thought the hon. Member had better mention names.

Mr. MCKENNA said he was surprised to find the right hon. gentleman so sensitive—he who had not hesitated to call those opposed to him traitors, pro-Boers, and Little Englanders. However, if he wanted the names he would say that the first witness called in defence of Dr. Irvine was Mr. W. Cook, J.P., Alderman of the City of Birmingham and chairman of the Hospital Saturday Fund in Birmingham.

Mr. CHAMBERLAIN: And chairman of the Liberal Association.

Mr. MCKENNA said that this information was not given in the report of what took place. The next witness was the honorary secretary of the institution, and the next Mr. Arthur Chamberlain, J.P. Perhaps the Vice-President of the Council would be able to explain to the House who it was that recommended this gentleman to be an inspector of schools.

Mr. CHAMBERLAIN complained that the hon. Member had given him no notice of this attack, but he happened to know something of the subject matter and he would state the facts to the House. He had never seen Dr. Irvine and knew nothing about him except that he had been appointed an inspector of schools. He had never recommended or suggested him for the appointment, and, indeed, had never even heard of his name until the hon. Member introduced it. It was unfortunate that Members below the gangway could not attack him without attacking other people. He did not mind these attacks, but he thought it was a distinct abuse of the privileges of the House to bring in the names of people who were in no way connected with the Colonial Secretary. The hon. Member had represented that Dr. Irvine was under a ban, that his character was under the consideration of the General Medical Council. As a matter of fact, the only charge against this gentleman was that of having infringed what he might call a trade-union rule of the medical profession. There was absolutely nothing against his private character. Certain gentlemen in Birmingham, among them his brother, Mr. Arthur Chamberlain, devised a new charity in Birmingham to secure for the working classes of the city the advantages of consultation with eminent practitioners which they could not have under existing circumstances without payment beyond their means. The object was to secure a gentleman of high professional reputation. Dr. Irvine was chosen as the first of these practitioners, and the moment he was chosen the greatest possible objection was taken on behalf of the medical profession in Birmingham. He did not wish to go into the matter in detail, but it must be evident to the House that the appointment of a gentleman to a position of this kind might have the effect of injuring the business of other private practitioners, and it was not unnatural that complaint should be made. The complaint was carried to the General Medical Council who, he understood, gave as their decision that if Dr. Irvine did not retire from the position they would strike his name off the Medical Register. Dr. Irvine, for good reasons no doubt, thought it his duty to bow to the decision of the Council and he gave notice to the charitable institution that he would be unable to continue his services to it. He believed that the institution had already appointed, or intended to appoint, another gentleman of professional eminence and he hoped it would find some one who would carry out the eminently beneficial objects which its promoters had in view. That was the whole story. It was in connexion with a story like this, a story of a charity in which men of all classes and all politics in Birmingham were concerned, that the hon. Member got up and with an air of mystery tried to make the House believe that he had discovered a plot in which the Colonial Secretary was concerned.

Sir WALTER FOSTER explained to the House the duties and powers of the General Medical Council and in particular the circumstances in which the Council might declare a registered medical practitioner to have been guilty of "infamous conduct in a professional respect."

Mr. CHAMBERLAIN, interrupting the hon. Member, asked whether he considered taking lower fees than were usual constituted "infamous conduct."

Sir WALTER FOSTER replied that he was merely quoting the words of the Medical Act and that it did not lie with him but with the General Medical Council to define what they meant. In this case the Council had found the charge proved and they might proceed to erase the name from the Register. Dr. Irvine had, as it were, been remanded for six months in order that he might have an opportunity of considering his position. They had here the decision of a judicial body so high that no judge of the land had ever ventured to question its decisions. On the contrary, the courts had always held that the Council were the only body competent to decide what was "infamous conduct in a professional respect." He submitted on purely public grounds that no person in such a position as this doctor, awaiting the judgment of the General Medical Council on a charge on which he had been found guilty, ought to have been appointed to a high public office, especially as the body which made the appointment, the Privy Council, was the body under which the General Medical Council worked.

Sir JOHN GORST said that Dr. Irvine had been selected from a large number of candidates for an inspectorship of schools by the Lord President of the Council as the man from his very *exceptional* qualifications best fitted for the office. He held a very distinguished degree of Trinity College, Dublin, and not being a man of great means he had supported himself before and after he had taken his medical degree by acting as a teacher and master in several secondary *schools in Ireland.* At the time the appointment was made the Lord *President* and he had not heard of this charge against Dr. Irvine.

Sir WALTER FOSTER pointed out that the Privy Council received the minutes of the General Medical Council.

Sir JOHN GORST said that neither the Lord President nor he had sufficient leisure to peruse the proceedings of the General Medical Council, but even if the matters alleged in the course of this debate had been brought to the notice of the *Board of Education* they would have seen in them no reason whatever for reconsidering their decision.

FRIDAY, MAY 24TH.

The Standard for Milk.

Mr. HANBURY, on being questioned with regard to this subject by Mr. LAMBERT, said that he was very anxious that there should be the fullest criticism of the report of the Committee before the standard was fixed, but he certainly hoped to have it fixed within a week after the close of the Whitsuntide Recess.

Scottish Health Bill.

On the motion of the LORD ADVOCATE a Bill was introduced and read a first time to amend the law in regard to the sewerage and drainage and water-supply of burghs in Scotland.

Watkins —On May 20th, Robert Webb Watkins, F R.C.S, J P, of Towcester, aged 76.

Williams —On May 21st, at 20, Windsor-place, Cardiff, John D. Williams, M.D, aged 36 years

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Parliamentary Intelligence.

HOUSE OF COMMONS.

THURSDAY, MAY 23RD.

Disease among the Troops in South Africa.

SIR WALTER FOSTER asked the Secretary of State for War if he could state the number of cases of typhoid fever and the number of deaths among the forces in South Africa during the month of April, and also the number of cases of plague and the number of deaths from that disease, up to the latest advices, among the soldiers and others engaged in the campaign.—Mr. BRODRICK replied: The returns for April received only take up to the 19th; there had been then 1052 admissions for enteric fever and 140 deaths. The numbers of cases of plague have, according to latest advices, been as follows—viz., 14 soldiers, 20 native drivers, and eight other employés; of seven deaths reported none are stated to have occurred among soldiers.—Dr. FARQUHARSON asked the Secretary of State for War whether he could state the number of sick in the 2nd Worcesters at Bloemfontein between April 4th and 27th, 1900, what were the total of enteric fever cases, and what the ratio of mortality was up to May 31st.—Lord STANLEY replied to the question, saying: The number of sick admitted to hospital between April 4th and 27th, 1900, was 94. It is not possible to differentiate the cases of enteric fever from the information at the disposal of the War Office, but up to May 31st there were 15 deaths from enteric fever.

Treatment of Tuberculous Carcasses.

Mr. FIELD asked the President of the Local Government Board whether he was aware that the late medical officer of health of the City of London stated in his annual report to the Corporation, 1900, that he would condemn all carcasses affected by localised tuberculosis; and, in view of the statement of the Royal Commission on Tuberculosis that such meat might be eaten with impunity, and seeing that the late medical officer of health of the City of London was paid part of his salary by the Local Government Board, would he state what steps the Board would take.—Mr. WALTER LONG said: I am aware of the statements made on this subject by the late medical officer of health of the City of London in his report for 1899, but I am not responsible for the views which he entertained. I may add that no part of his salary was paid by the Local Government Board.

Educational Appointment for Dr. Henry Ward Irvine.

On the motion for the adjournment of the House for the Whitsuntide vacation,

Mr. MCKENNA called attention to the appointment of Dr. Henry Ward Irvine as one of His Majesty's inspectors of schools. He gave to the House an account of the proceedings before the General Medical Council when Dr. Irvine was charged with unprofessional conduct in connexion with an institution in Birmingham and the Council found the charge proved and suspended further proceedings in the case for six months, and explained that since then Dr. Irvine had withdrawn from the institution and accepted this appointment. The hon. Member submitted that Dr. Irvine should not have received the appointment whilst a charge of this kind was hanging over him. He had no wish to mention the names of the persons who were interested in this gentleman.

Mr. CHAMBERLAIN said that as the whole speech was an insinuation he thought the hon. Member had better mention names.

Mr. MCKENNA said he was surprised to find the right hon. gentleman so sensitive—he who had not hesitated to call those opposed to him traitors, pro-Boers, and Little Englanders. However, if he wanted the names he would say that the first witness called in defence of Dr. Irvine was Mr. W. Cook, J.P., Alderman of the City of Birmingham and chairman of the Hospital Saturday Fund in Birmingham.

Mr. CHAMBERLAIN: And chairman of the Liberal Association.

Mr. MCKENNA said that this information was not given in the report of what took place. The next witness was the honorary secretary of the institution, and the next Mr. Arthur Chamberlain, J.P. Perhaps the Vice-President of the Council would be able to explain to the House who it was that recommended this gentleman to be an inspector of schools.

Mr. CHAMBERLAIN complained that the hon. Member had given him no notice of this attack, but he happened to know something of the subject matter and he would state the facts to the House. He had never seen Dr. Irvine and knew nothing about him except that he had been appointed an inspector of schools. He had never recommended or suggested him for the appointment, and, indeed, had never even heard of his name until the hon. Member introduced it. It was unfortunate that Members below the gangway could not attack him without attacking other people. He did not mind these attacks, but he thought it was a distinct abuse of the privileges of the House to bring in the names of people who were in no way connected with the Colonial Secretary. The hon. Member had represented that Dr. Irvine was under a ban, that his character was under the consideration of the General Medical Council. As a matter of fact, the only charge against this gentleman was that of having infringed what he might call a trade-union rule of the medical profession. There was absolutely nothing against his private character. Certain gentlemen in Birmingham, among them his brother, Mr. Arthur Chamberlain, devised a new charity in Birmingham to secure for the working classes of the city the advantages of consultation with eminent practitioners which they could not have under existing circumstances without payment beyond their means. The object was to secure a gentleman of high professional reputation. Dr. Irvine was chosen as the first of these practitioners, and the moment he was chosen the greatest possible objection was taken on behalf of the medical profession in Birmingham. He did not wish to go into the matter in detail, but it must be evident to the House that the appointment of a gentleman to a position of this kind might have the effect of injuring the business of other private practitioners, and it was not unnatural that complaint should be made. The complaint was carried to the General Medical Council who, he understood, gave as their decision that if Dr. Irvine did not retire from the position they would strike his name off the Medical Register. Dr. Irvine, for good reasons no doubt, thought it his duty to bow to the decision of the Council and he gave notice to the charitable institution that he would be unable to continue his services to it. He believed that the institution had already appointed, or intended to appoint, another gentleman of professional eminence and he hoped it would find some one who would carry out the eminently beneficial objects which its promoters had in view. That was the whole story. It was in connexion with a story like this, a story of a charity in which men of all classes and all politics in Birmingham were concerned, that the hon. Member got up and with an air of mystery tried to make the House believe that he had discovered a plot in which the Colonial Secretary was concerned.

Sir WALTER FOSTER explained to the House the duties and powers of the General Medical Council and in particular the circumstances in which the Council might declare a registered medical practitioner to have been guilty of "infamous conduct in a professional respect."

Mr. CHAMBERLAIN, interrupting the hon. Member, asked whether he considered taking lower fees than were usual constituted "infamous conduct."

Sir WALTER FOSTER replied that he was merely quoting the words of the Medical Act and that it did not lie with him but with the General Medical Council to define what they meant. In this case the Council had found the charge proved and they might proceed to erase the name from the Register. Dr. Irvine had, as it were, been remanded for six months in order that he might have an opportunity of considering his position. They had here the decision of a judicial body so high that no judge of the land had ever ventured to question its decisions. On the contrary, the courts had always held that the Council were the only body competent to decide what was "infamous conduct in a professional respect." He submitted on purely public grounds that no person in such a position as this doctor, awaiting the judgment of the General Medical Council on a charge on which he had been found guilty, ought to have been appointed to a high public office, especially as the body which made the appointment, the Privy Council, was the body under which the General Medical Council worked.

Sir JOHN GORST said that Dr. Irvine had been selected from a large number of candidates for an inspectorship of schools by the Lord President of the Council as the man from his very exceptional qualifications best fitted for the office. He held a very distinguished degree of Trinity College, Dublin, and not being a man of great means he had supported himself before and after he had taken his medical degree by acting as a teacher and master in several secondary schools in Ireland. At the time the appointment was made the Lord President and he had not heard of this charge against Dr. Irvine.

Sir WALTER FOSTER pointed out that the Privy Council received the minutes of the General Medical Council.

Sir JOHN GORST said that neither the Lord President nor he had sufficient leisure to peruse the proceedings of the General Medical Council, but even if the matters alleged in the course of this debate had been brought to the notice of the Board of Education they would have seen in them no reason whatever for reconsidering their decision.

FRIDAY, MAY 24TH.

The Standard for Milk.

Mr. HANBURY, on being questioned with regard to this subject by Mr. LAMBERT, said that he was very anxious that there should be the fullest criticism of the report of the Committee before the standard was fixed, but he certainly hoped to have it fixed within a week after the close of the Whitsuntide Recess.

Births, Marriages, and Deaths.

BIRTHS.

MORRISON —On May 24th, at Brighton road South Croydon, the wife of Alexander Morrison, M R.C S, L.R C P, of a daughter

WELLBY —On May 29th, at 27th, St. Julian's Farm road, West Norwood, S E, the wife of Stanley Wellby, M.B Oxon, of a daughter

WOODMAN —On May 27th at New road, Rochester, the wife of William James Woodman, M R.C S, &c., of a son.

MARRIAGE.

WATSON—GREEN —On May 13th, at Algiers, first at the British Consulate and afterwards at the Church of the Holy Trinity, George Samuel Watson, M R.C S, of Tunbridge Wells, to Edith Sarah Green, of The Limes, Hurstpierpoint.

DEATHS.

MACLEROY —On May 19th at Oakford House, King's Teignton, South Devon, Arthur Lloyd MacLeroy, M A. Oxon., L.S A., L.A.H Dub., in his 49th year

SKIMMING —On May 23rd Robert Skimming, M.D, F R C S Ed, of Tudor Lodge, East Molesey, aged 58.

WATKINS.—On May 20th, Robert Webb Watkins, F R.C S, J P, of Towcester, aged 76

WILLIAMS —On May 21st, at 20, Windsor-place, Cardiff, John D Williams M.D, aged 36 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths

Notes, Short Comments, and Answers to Correspondents.

APHASIA OF HYSTERICAL ORIGIN.

Aphasia of hysterical origin is rare, though phenomena of an allied nature, such as aphonia and mutism of varying degrees, are not uncommon in hysteria Dr. Georges Guillain of Paris has published in the *Revue Neurologique* of April 30th a case of hysterical aphasia occurring in a man and showing several features of interest. The patient was a workman of temperate habits, free from syphilis, and in the enjoyment of good health In 1897 he heard of the death of his brother, which so prostrated him that he was obliged to take to his bed, after which he found himself incapable of walking for a period of 15 days. He then got well and was able to resume his work. Two years after he received bad tidings concerning a nephew. He had a violent altercation with his sister about this, and went to bed angry and excited, waking next morning with a violent headache and finding that he had lost power over his legs so that he could not walk. This condition had lasted for two months when he was admitted to hospital in March, 1900, and on examination he was found to present a slight hemiplegia of the right side of the body and complete aphemia (glosso-kinæsthetic aphasia of Bastian). His mind was clear throughout the present illness and his wife asserted that he never had lost consciousness or suffered from coma during the illness. For six weeks after admission there was paralysis of the rectal and vesical spincters. He could not well understand what was said to him. There was no dysphagia. He gradually improved after a few weeks' stay in a hospital and after six months he was able to walk. He could not move his tongue when asked to, but could give either hand or both hands when requested. But when asked to lower the hand he proffered the other hand, when asked to open the hand he opened his mouth, asked to close the hand he made no response, asked to place his left hand on his head he placed the right hand on the chin, and when told this was wrong he placed the left hand on the chin. Hearing was good. He could utter the words "Yes" and "No" and a few uncouth sounds of one or two syllables, but of no significance. He could not repeat words uttered in his presence or sing. He was ignorant of reading and writing and therefore could not be tested for knowledge of printed words. On being shown a picture of a horse and a bottle he nodded recognition when the correct name was given to each of these in his presence, but he turned away in disgust when the picture of a boat or of a house was shown. On being shown a clock and asked the time his reply showed that he confounded the hour and minute hands Shown a rhinoceros carved in wood he admitted it was not a lion or a bear, but said "Yes" when asked if it was a rhinoceros. On examination it was found that the right hand and arm were cyanosed and cold, and the same applied to the right foot and leg. With the dynamometer the right grip registered 16 kilogrammes and the left 32 kilogrammes. There was no disturbance of sensibility, and the stereognostic sense was normal. The tendon-reflexes (knee-jerk, tendo-Achillis-jerk, and elbow-jerk) were exaggerated on the right side. Gait, at the termination of his stay in hospital, was normal. There were no signs of visceral or organic disease. Babinski's great-toe reflex was present, and this confirmed the diagnosis of hysterical hemiplegia and aphasia which was made. Light and colour perception was normal, and the general health was good. Dr. Guillain refers to cases of aphasia and word-deafness of hysterical origin recorded by Raymond, aphemia of similar origin recorded by Janet and Bernheim, and agraphia of hysterical origin recorded by Charcot, Déjerine, and others, which have interesting analogies with the present case.

KELENE.

To the Editors of The Lancet.

Sirs,—I shall feel grateful to any of your medical or dental readers if they will give me their experience of the usefulness of kelene as a general anæsthetic when administered by means of a suitable face-piece I am a country practitioner with no assistance and therefore fight shy of chloroform as much as possible. How long can a patient with safety be kept under kelene? I understand narcosis is produced as quickly as with nitrous oxide.

I am, Sirs, yours faithfully,
May 28th, 1901. M. W. D.

"PLACE OF RESIDENCE FOR A RETIRED SURGEON."

To the Editors of The Lancet.

Sirs,—In The Lancet of March 30th, p. 937, "P. P.," a retired surgeon, asked for information as to a good residence to which to retire and was advised, I think, to try Branksome, near Bournemouth. With regard to the last-named I have been there twice, on account of my health, once when it was so wet and cold that I was obliged to leave and once when it was so wet and hot that I was likewise obliged to make my exit. May I suggest the suburbs of some good city, such as Worcester, as a trial. Malvern (within eight miles), and especially West Malvern (about 1000 feet above sea level), are worth knowing. At the latter there is excellent accommodation at the Westminster Arms, kept by Mr. Martin, as well known in America as in England I am told. Dr. Charteris in the chief work on health resorts states, I remember that he knows no place better than Malvern to recuperate jaded health in certain states. Were it not for the fact that the local authorities are in a somnolent condition, that scutch was not burning all day in private gardens, and that the public gardens were not closed during half of the year, I believe it would be one of the most favoured places in England.

I am, Sirs, yours faithfully,
Worcester, May 21st, 1901. W. Woodward, M.D St. And.

SUGGESTIONS WANTED.

To the Editors of The Lancet.

Sirs,—I am a medical man, aged 34 years, married, a very moderate drinker, an athlete, and in extremely good muscular condition and well developed in every respect, yet the curse of my life is hyperidrosis, the very slightest exertion causing me to sweat most profusely. I have limited my fluid to six ounces per day for days on end without any benefit. I have given every drug in the British Pharmacopœia a fair trial without benefit. What is it, and what can I do? I am an open exponent of any theory existant, and would be eternally grateful for any suggestions which would bring me relief.

I am, Sirs, yours faithfully,
May 28th, 1901. Veldt.

HEPATIC ENLARGEMENT IN TYPHOID FEVER.

To the Editors of The Lancet.

Sirs,—Can any of your readers refer me to literature bearing upon hepatic enlargement in typhoid fever?

I am, Sirs, yours faithfully,
May 27th, 1901. D. A. A.

THE PREVALENCE OF RESPIRATORY DISEASES NEAR THE METROPOLIS.

To the Editors of The Lancet.

Sirs,—I am unable to lay my hands on the Registrar-General's reports which some of your readers probably have at their fingers' ends. Could some one kindly inform me of the various districts round London within a nominal hour's journey where respiratory diseases are least prevalent? What I want to know especially is the best place or places for a patient to live in who suffers from bronchitis every winter.

I am, Sirs, yours faithfully,
May 28th, 1901. X. Y. Z

◆

General Practitioner would be glad to receive advice as to the best method of treating asthma which comes on in the early hours of the morning—from 2 to 5 a.m.—in connexion with gouty nephritis in a man, aged 65 years. There is marked albuminuria with casts, the heart is weak and irregular, and there is a little œdema of the legs

Mr. H. Smith.—We have noticed the Progressive Medical Alliance in properly abusive terms on several occasions, but the "experts and specialists" who do the work of the Alliance are not really medical men and women and cannot be removed from a Register on which they have no place.

C. W. W.—The institution in question is founded for the practice of mischievous quackery. It is astonishing that respectable newspapers can be found to insert such advertisements.

Hampshire—Six shillings is a fair price. The essential point is that all the medical men in the neighbourhood should be absolutely agreed upon the point.

Communications not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

During the week marked copies of the following newspapers have been received:—*Mining Journal, Leeds Mercury, Local Government Journal, Windsor and Eton Express, Vancouver Daily Province, City Press, Liverpool Daily Post, Reading Mercury, Yorkshire Post, Hertfordshire Mercury, Cornish Echo, Shanklin Gazette, Weekly Free Press (Aberdeen), Sunday Special, Lancaster Guardian, &c., &c.*

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (3rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.).

TUESDAY (4th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

WEDNESDAY (5th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.).

THURSDAY (6th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

FRIDAY (7th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

SATURDAY (8th).—[illegible] St. Thomas's (2 P[illegible] Charing-cross (2 [illegible] London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

WEDNESDAY (5th).—OBSTETRICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8 P.M. Specimens will be shown by Dr. Galabin, Dr. Donald (for Dr. Fothergill), Dr. H. R. Andrews, and Mr. S. Boyd (introduced by Dr. A. Routh). Paper:—Dr. Donald: Fibroid Tumours complicating Pregnancy and Labour.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (3rd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. J. F. Payne: Consultation. (Skin.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. S. Edwards: Affections of the Prostate.

TUESDAY (4th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. W. Ewart: Consultation. (Medical.)

WEDNESDAY (5th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. E. W. Roughton: Consultation. (Surgical.)

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Horton-Smith: Aortic Aneurysm.

THURSDAY (6th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. Hutchinson: Consultation: (Surgical.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. C. B. Keetley: Hip Disease.

CHARING-CROSS HOSPITAL.—4 P.M. Dr. Murray: Medical Cases. (Post-Graduate Course.)

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Dewar: The Chemistry of Carbon.

FRIDAY (7th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. H. Tilley: Consultation. (Throat.)

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

ABSTRACT OF

An Address

ON

SOME OF THE ANATOMICAL ASSOCIATIONS OF THE KIDNEYS, FROM A SURGICAL POINT OF VIEW

Delivered before the Cardiff Medical Society on June 6th, 1901,

BY EDMUND OWEN, F R C S ENG ,
SURGEON TO ST MARY S HOSPITAL, LONDON

NERVE ASSOCIATIONS OF THE KIDNEYS

IN a large proportion of cases of renal disease the most prominent symptom is the subjective one of *pain* At any rate, it is usually this which brings the patient to the surgeon, and makes the latter set to work to discover objective signs which may lead him to a correct conclusion as regards its cause In speaking of the anatomical associations of the kidney, therefore, particular attention must be paid to the nerves, which not only associate the kidney with the neighbouring parts, but also keep the kidneys in harmonious working with each other The nerves are derived from the sympathetic plexus in front of the upper part of the abdominal aorta, and into this plexus run branches of the splanchnics, the pneumogastrics, and also, indirectly, of the spinal nerves These various filaments join in an entanglement from which the instruments of the most skilled dissector are unable to sort or to unravel them, and each abdominal viscus takes filaments from this interlacement according to its needs Remembering that the testis was developed in close association with the kidney, it is not surprising that the nerves of the renal plexus are intimately connected with those of the spermatic plexus And to this association of nerves is due the explanation of the pain in the testicle to which renal calculus often gives rise

With an innervation scheme in which medullated and sympathetic filaments are thrown with ganglia into a central pool from which each viscus helps itself, as it were it can hardly be matter of surprise if the result does not always work out quite satisfactorily in a clinical sense Of course, such an arrangement of nerve tissue could not possibly suffice for supplying motor influences to the voluntary muscles of the body which have to contract with energy and precision, nor would it serve for the prompt and precise conveyance of sensory stimuli to the brain, but for quiet-going viscera in smooth working-order the scheme answers perfectly Still, when disturbance arises in the affairs of any individual viscus, confusion is apt to occur, and errors of diagnosis and treatment are apt to ensue in consequence Supposing that a calculus is forming in one kidney, a somewhat urgent and disquieting message is transmitted to the solar plexus This is an unwonted occurrence, and the plexus is as unprepared for its reception and as incompetent to deal with it as, in somewhat similar circumstances, was that mixed department in Pall Mall known as the War Office All is muddle and confusion , and when an explanation is demanded as to why and where the disturbance arose, and as to the precise cause of it, answer comes that it was on this side or on that side—it may be right and it may be wrong In the clinical case which I am about to relate the answer was as incorrect as it could be —

A healthy looking man 36 years of age was admitted to S Mary s Hospital on Oct 7th, 1897 The notes say that he first felt dull pains in his back 10 years previously, and that about five years later he had a bad attack of renal colic on the left side , that he had several like attacks each year (which were always associated with vomiting), and that he had passed blood and many small calculi on various occasions For the purpose of this paper, I wrote the other day to the patient for his own account and this is what he said —" These later attacks were very severe and always confined to the right side, and relief was only procurable by applying linseed poultices and turpentine to the back, and then to the front; the marks of which were on me when I was examined " Yes, this was so at the time of his admission the skin of the front and back of the right renal region was deeply stained by the marks of fomentations, and the patient was quite satisfied in his own mind that the small calculi, which he had passed from time to time, had come from the *right* kidney Objective signs gave no help in the matter of localisation On Oct 13th the bladder was sounded, with a negative result, and a few days afterwards I explored the right kidney from behind, finding it larger than normal but otherwise healthy The patient, a highly intelligent man, was, like myself, a good deal disappointed at this blank operation , but he promised to come into hospital again in a few weeks so that I might explore the other kidney He was a bank clerk, and he fully understood that he had on this occasion, at any rate, made a mistake in his calculation

Faithful to his promise, he came back towards the end of the following month, saying that since the operation he had been " perfectly comfortable," but that on one occasion he had passed some blood On Nov 29th I cut down upon the posterior surface of the *left* kidney, extracting a branching, coral like calculus and several small calculi, and also evacuating a renal abscess of considerable size The stone was phosphatic, and it weighed over 400 grains Seeing how extensively this kidney was diseased, I hesitated whether I should take it away or not, but eventually decided to give it a chance So I deluged its interior with hot sterilised water, and in this way washed out some more small stones A drainage tube was introduced into the kidney and the surface wound was closed Whilst in the hospital the man occasionally passed small calculi per urethram ; his urine contained some pus, and at times a little blood There was, moreover, constant leakage from a sinus which persisted in the loin He left the hospital in January fairly well, except for the annoying sinus This sinus continued to leak ; so he came into the hospital again in February, 1898, in order that I might relieve him of that annoyance by removing the kidney But when I examined him under an anæsthetic, and had explored the kidney with my finger, I had not the heart to perform the nephrectomy, as I found that a considerable amount of firm and apparently healthy tissue still remained So I chased out a few more small stones, and determined to give the damaged organ yet another chance The man stayed only a few days in hospital, and shortly afterwards resumed work at the bank, where he continued at business for a little over a year, the sinus oozing all the time into pads of absorbent dressings To use his own words, ' After the Easter holidays, 1898, I continued daily to travel up and down to the City, without a single exception, changing the bandage at midday, and on going to bed my wife used to thoroughly wash and irrigate the wound and to pass a probe down I never became offensive, and I had fairly good health until April, 1899 Then I came to see you when you immediately operated, and removed the kidney, April 17th, 1899, after which the wound healed completely " He is now perfectly well, his large right kidney being quite up to the work thrown upon it—even after a 25 mile bicycle ride

An interesting feature of this case is that though the man was working in a City office through the hot months his fellow clerks never noticed any unpleasant odour , if an intelligent man with a renal fistula takes care of himself, his wound need not become septic or his leaking urine offensive

I am well aware that it is not a very unusual occurrence for a surgeon to operate upon the wrong kidney in his search for a stone , but I do not think that a more conspicuous instance than this, of the untrustworthiness of the subjective symptom of *pain* in renal calculus, is likely to be forthcoming Subjective signs are proverbially untrustworthy through the whole range of surgery , but in the case of the kidneys, which have drawn their nerves blindfold from the epigastric pool, it is small wonder if, in the absence of objective signs, patient and surgeon are sometimes led by them to make serious mistakes

VASCULAR ASSOCIATIONS

In one matter in particular the vascular associations of the kidney are important from a surgical as well as from a medical point of view Let us take, for instance, the case of a man with old standing stricture of the urethra that is to say a surgical case of damaged kidneys, or, if you will, a man with early Bright's disease—a sufficiently vague term The kidneys are just able to do the amount of excretory work which is demanded of them, but they have absolutely no reserve of physiological energy. The man indulges in a drinking bout, or, out at work, he gets wet through, and is suddenly attacked with sub-acute nephritis; and, perhaps, with complete suppression of urine. What is to be done for him? The intestinal canal and the skin are always ready to assist the kidneys if properly called upon, and, therefore, a full dose of calomel and jalap, and a hot-air bath may suffice to help the comatose patient over this very serious crisis. But there is something yet that may be done towards relieving the vascular engorgement of the kidneys and putting them in working order once more. The practitioners of bygone days would have resorted to venesection, and I am not sure that I should not do so myself, for I am a keen advocate for this "old-fashioned remedy out of date," as the late Dr. Hare called it. But the method to which I desire here to refer is the application of a score of leeches, or the efficient employment of wet or dry cupping over the loins.

If we take down from the dusty shelf the handbook of "Anatomy" which was so familiar to us in our student days—the only book in our old professional library, by the by, which has not become hopelessly out of date—we shall find (what we have never forgotten) that the kidney is supplied by the renal artery, and that the mass of the loins is supplied by the lumbar branches of the abdominal aorta. And from this brief description it might be taken as implied that the vascular systems of these two areas are separate and distinct. But if it were so, the application of leeches or cupping-glasses to the loins could have but very slight influence upon the renal engorgement. In his valuable work upon the "Arteries" which Robert Harrison published in Dublin in 1828, he specially called attention to the fact that the lumbar branches of the aorta helped in the supply of the kidneys—that is to say, that a free communication took place between the vessels of the abdominal wall and those of the abdominal viscera. Sir William Turner also, when a Demonstrator of Anatomy in the University of Edinburgh, did a great deal of work at this subject, publishing the results of his injections and dissections in the *British and Foreign Medico-Chirurgical Review* of 1863. He gives an account of the parietal and visceral anastomoses from diaphragm to perineum, but just now we are concerned with the scheme only so far as it affects the kidneys. The renal artery from the abdominal aorta having given the kidney all that it needs, sends branches through the fibrous capsule to join in an extensive anastomosis which the Edinburgh demonstrator named the sub-peritoneal arterial plexus. The chief vessels in this anastomosis of parietal with visceral arteries, are the phrenic and the lower intercostal arteries, and the upper lumbar branches of the aorta. Together with this arterial anastomosis there is, of course, a free communication between the venous plexus of the parietes and that of the kidney. And thus it comes about that the application of leeches or cupping-glasses to the loins, has an equally direct and important influence in the relief of renal engorgement. A knowledge of this piece of anatomy explains, moreover, how it is that a turpentine fomentation or a mustard plaster, by causing a dilatation of the surface-capillaries, and getting them filled from the renal vessels, thereby relieves the congestion of the kidneys, and produces a valuable diuretic effect.

ASSOCIATIONS WITH THE COLON.

I wonder if in Glamorganshire surgeons have ever met with such experience as that through which I have at times, unhappily, had to pass in London, of several of his cases, hospital cases and private cases, actually or apparently going wrong together? When clinical records, bedroom reports, thermometric charts and x-ray shadow-prints all seem to be pointing their fateful fingers at one and the same time! So far as my personal knowledge goes, I am apparently the only operating surgeon in London who has met with this experience; and I am heartily glad of it, for I would not wish my worst enemy to undergo it. The feeling, as I have experienced it, is such as to make a surgeon wonder if he did not, after all, commit a grievous error in the choice of his profession, and to induce him at once to throw it up. I ask if anyone in this part of the Principality has ever gone through such sad experience, because I am now amongst my Celtic congeners, and I think it just possible that the Celtic temperament may have something to do with so unhappy a state of affairs. Venturing to assume from your silence that at least one of you has known similar fits of depression in connexion with his professional work, I at once feel less lonely; and, being thus enabled to speak in the first person plural, instead of as a solitary individual, I will ask if we are to explain the condition on the theory of the possible inheritance of some mysterious psychic legacy from an ancestral Druid of dyspeptic nature, who, becoming discredited in his profession because of his having persistently made wrong prognoses from the flight of the birds, or from the curl of the smoke of his sacrificial fires, fled despondent from his shady grove and turned his wasting energies perchance into the more honest and healthful paths of agriculture.

At any rate, just before the last period of the gathering of the sacred mistletoe, I was passing through such a time of trial as that just referred to, and when my cup of clinical misfortune seemed already full, I became associated with a peculiarly calamitous case, which I will report to you after I have made one more digression. Before relating it, I would ask how it is that in London the operative experience of almost every surgeon is apparently so extremely happy? The published reports of contemporary surgical practice seem to indicate an unvarying and almost monotonous record of success. Nevertheless, when I am reading some professional essay which is based upon a series of universally successful cases, which boldly conveys, or like an Æsop's fable ends up with a puffy *Moral*, I am now and then tempted to wonder if in the compilation of it the diplococcus of the imaginative faculty has not here and there been allowed to get the better of the germ of truth. But about this "germ of truth." It is strange how little we hear of it now, even in laboratory work. I understand that it is most difficult of cultivation; that it will not grow in hay-broth or gelatin, or upon fresh-cut slices of potato. So delicate is it that there is a risk of its altogether disappearing out of cultivation, like the beautiful pseudo-narcissus, or Tenby daffodil, that plant so dear to our illustrious friend Dr. Vachell, who, in the twenty-sixth volume of the Cardiff Naturalists' Society, tells us that this, our only native narcissus, which used to thrive so well in South Wales, has now almost entirely disappeared from the land it loved, by reason of the attacks made upon it by scientific and commercial botanical thieves, who came from London and other parts of the adjacent country of England in search of the precious bulbs. Let us hope, for the sake of the Principality, that the day may be far distant when English bacteriologists and other men of science will come to Wales in search of the few remaining specimens of the germ of Truth!

This is the case to which I was referring:—On the first day of last December I saw with my colleague Dr. Sidney Phillips a clergyman, 42 years of age, an unusually well-made, muscular man, who, except for a somewhat "worn" expression, looked as if he were in perfect health. This is the history that Dr. Phillips gave me of his case: "He has always enjoyed good health till the beginning of the spring of 1900, when he began to get pain in the back when bicycling. On July 3rd, 1900, he travelled by train to Llandudno from Northampton and experienced pain on the journey, and this became more severe in the evening. Since July he has been constantly in pain, but it has been most severe in the evenings and nights. About the 6th of October the pain became a good deal worse; he is doubtful if exercise brings it on, but he feels it more when he has had a railway journey. The pain goes into his left thigh and testis. He thinks that he has never had hæmaturia The urine deposited phosphates with heat; there was no albumin in it or sugar. He used to weigh 13 stones, but on October 17th, 1900, his weight was only 12 stones 8 pounds. He had 'gravel' at the age of 25, and since then he has not held his water well, never going through a night without having to get up to pass urine. He does not think the frequency of micturition has become more marked of late." Dr. Phillips examined him under an anæsthetic on Oct. 17th, as he held his abdominal muscles so tense on the left flank that no deep palpation was possible; but nothing abnormal could be detected, neither fulness nor tumour. On Dec. 1st Dr. Phillips received a letter from the medical man who had been looking after him in the country in which it was stated that there had been blood in the urine on several occasions. The opinion of the medical man was that the cause of the trouble was renal calculus. When I examined him there seemed to be so much tenderness in the front and back of the lumbar region that I was not able to make a thorough exploration. The muscles were rigid and I could not thrust my fingers into the renal region. The patient told me of pains running into the thigh and into the testis, and I also arrived at the conclusion that he probably had a stone in his left kidney. Accordingly, on Dec. 5th in the presence of Dr F[illegible] made an incision from the tip of the last rib to [illegible] border of the erector spinæ, but on cutting dow[illegible] posterior surface of the kidney I could detect no stone. I then loosened the connexions of the kidney and brought it out on to the surface, and still finding no stone I incised the outer border of the kidney and introduced my finger into the interior, but with a like negative result Greatly disappointed, I closed the wound, inserting a gauze plug which passed into the interior of the kidney.

Subsequently to the operation the patient suffered considerably, so that several injections of morphia had to be given him But althougt [illegible] of the wound remained [illegible] dition caused great anxiet[illegible] nothing to suggest that his failure to improve was due to septic causes, but he became more depressed and feeble day by day Rectal stimulation was resorted to, as was also the intravenous injection of a hot saline solution; but all to no purpose. He died about midnight on Dec 8th On the afternoon of that day I was examining for the Bachelor of Surgery Degree of the London University, and during an interval in the examination I told my colleagues how a splendidly developed man was slipping through my fingers after a disappointing operation for supposed renal calculus. My co-examiners were human and sympathetic, and one of them remarked that the unhappiness of a case of this sort is sometimes greatly softened by the disclosures of the post-mortem examination And so it was here; for the [illegible] owing into the [illegible] of the kidney, [illegible] ere so hidden in the [illegible] vault as not to be easily recognisable, though one of them was as large as a small cocoanut "The kidney was found to be quite normal and only showed the incision of the operation"

[illegible]

did not exist, was most welcome to everyone concerned!

From a surgical point of view, the most important of the anterior relations of the kidneys is certainly the large intestine—the ascending part of the colon lying in front of the right kidney, and the descending part in front of the left

On New Year's Day of 1895, a man, aged 55 years, was admitted into the Thistlethwayte Ward of St Mary's Hospital. He looked very worn and ill, and he remarked that he had lost four stones in weight during the past three years He said that his troubles began about four years [illegible] e right loin, which some[illegible] but generally shot down [illegible] me and went irregularly, lasting six or ten minutes and disappearing completely between the attacks He had steadily got worse, and a little more than a year ago he went into a large London hospital, where the surgeon, under whose care he was, told him that his distress was due to the fact that he had a "floating kidney," and that it ought to be cut down upon and stitched in its proper place To this operation he said he submitted, and a long, linear scar running obliquely over his right lumbar region seemed to confirm this statement The man further said that the very day after that operation he had recurrence of his old pains as severely as ever, and that on informing his surgeon of this, he had received the explanation that the "kidney must have broken loose again" From that moment it was recognised that the operation had produced no improvement whatever [illegible] which were steadily increasing t[illegible] tion upon the kidney, continued [illegible] that when he applied for a /mis[illegible] he compared them to "a thou[illegible] been troubled with loose, blood stained actions of the bowels On examination, a circumscribed tumour could be felt deeply in the region of the ascending colon, well above the level of the cæcum It was hard and tender, and was evidently the starting point of all his pains Whilst examining this mass, it was noticed that distended pieces of intestine in the neighbourhood were struggling to rid themselves of a collection of gas which was apparently divided up into hard, ball-like masses Indeed, so vigorously was the peristaltic action being carried on, that the gas was locked up in the segments of the bowel under such tension as to convey at a first touch, the idea of the balls being solid. But they were resonant on [illegible] presently changed their position or dis[illegible] The man was given to understand that [illegible] he had a cancerous mass which was blocking his bowel, and that though, possibly, it could not be removed, still some operation might be performed with the view of getting the contents of the bowel beyond the blockage, or of securing for them an easy and painless outflow.

On Jan 4th, therefore, a free incision was made through the right semilunar line, and a hard mass of the size of the fist was found in the colon as it ascended in the renal region I proposed short-circuiting the ileum with the colon beyond the obstruction, but on one of my colleagues urging that this could afford the patient but brief or imperfect relief, I resected the cancerous bowel and connected the divided ends of the colon by a Murphy's button. The growth proved to be a columnar epithelioma which almost entirely blocked the passage Below the obstruction the muscular wall of the intestine was greatly thickened, with the design of forcing onwards the liquid and gaseous contents Unfortunately the man died. On the evening before his death there was a slight escape of feculent fluid from the wound, and the conclusion formed was that the splice was not watertight At the post-mortem examination it was found that a perforation had occurred upon the distal side of the bowel, where the thin intestinal wall had pressed against the edge of the button. The man had been so weak, however, when the discharge was noticed, that it was not considered practicable to open up the wound and examine for the seat of the leakage

Having told you that this case ended fatally because of the edge of the metal button causing a perforation of the bowel (for the occurrence of which I readily accept the blame) it is obvious that I do not cite this report with any thought of building u[illegible] it with the idea of ma[illegible] surgeon who, about a [illegible] carcinoma of the asc[illegible] But I bring it forth f[illegible] well illustrates my Paper.

A Clinical Lecture

ON

RETENTION OF URINE.

Delivered at University College Hospital on May 20th, 1901,

By CHRISTOPHER HEATH, F.R.C.S ENG,

CONSULTING SURGEON TO THE HOSPITAL AND EMERITUS PROFESSOR OF CLINICAL SURGERY.

GENTLEMEN,—I am going to speak to you this afternoon on a disorder which must be interesting to every medical man and of which you may very likely have to treat cases directly you enter upon practice. By retention of urine is meant a condition in which the bladder does not extrude its contents I do not intend to day to speak about the kidney; I am confining my attention to retention of urine by the bladder, and it will be convenient to consider the male bladder first of all and to speak of it at different ages

In children you occasionally meet with retention from a tight foreskin When this occurs, the infant very soon after birth is noticed not to be passing urine or only very little, and possibly the foreskin is what is termed "ballooned" The treatment is simply to dilate the orifice with a pair of forceps, or, if you choose you may circumcise the child; but, in my opinion, dilating the orifice does just as well and an "operation" is avoided. Later in life a child, if it does not pass urine, may have a calculus in the urethra Calculi are formed, as we know, even before birth, and occasionally a small uric acid calculus passes into the urethra and becomes fixed there. The narrowest point of the urethra is at the meatus, and you may anticipate that the stone if it lodges at all will be found near the meatus. I remember a case which was brought here by a medical man, who had not detected a calculus which was present because he had not put a probe into the orifice. After, however, I had done that I found a little calculus which was easily removed by a pair of forceps. It has been suggested to make a nick in the orifice, and, though it is but rarely necessary to do this, you should remember to make the nick downwards where you will do no harm; if you cut upwards you will be cutting into the vascular tissue of the glans.

There is one form of retention of urine in the child concerning which you must be on your guard, and that is the possibility that a thread may have been tied round the penis. This happens generally in children who have been punished for wetting the bed, the child in desperation tying a thread round his penis to prevent this occurrence. I believe, however, that it may happen in other ways. I had a child brought to me at my house with the glans penis hanging merely by a few threads of cellular tissue. I accordingly *snipped the glans penis away with a pair of scissors and* found that there was a long, light-coloured hair around the part. We could not get any history and I did not wish to pursue inquiries. The entire glans, however, is in the College of Surgeons Museum, and the patient recovered and passed urine all right.

In considering retention in the adult I will take, first, the case of the young adult, and in most of these instances retention is the result of gonorrhœa. It may be in the early acute stage of gonorrhœa, or it may be in the later stage when the inflammation has travelled up the urethra and affected the prostate. In the early stage one is seldom consulted, because the *ardor urinæ* is naturally looked upon by the patient as incidental to his complaint. When it comes to the prostate being inflamed and enlarged the patient may have retention and then the case becomes serious. So that in all cases of retention in the young adult you will do well to place your finger in the rectum to see if there be a tender and somewhat enlarged prostate. You may detect the presence of matter, and if so you may open the abscess into the rectum or through the perineum. Perhaps you may not be able to detect matter which, however, is present, and then it may be necessary to pass a catheter. I do not know that it matters very much which kind of catheter you use—the English gum-elastic catheter of about No. 7 without the stylet is what I prefer. If the catheter has been introduced carefully it will probably pass the prostate, and it may and very likely will burst the abscess into the urethra and do all that you want for the case. That, of course, is the form of retention of urine which we meet with in the later stage of gonorrhœa, but let me remind you that prostatitis may take place from other causes. Sitting on damp seats or on wet grass may set up a prostatitis without the slightest reflection upon the patient's character.

Another of the commoner forms of retention of urine met with in gonorrhœa is, I think, the spasmodic variety. The man has passed through the usual experiences suffered in gonorrhœa and has knocked off his liquor for a considerable time, and in due course is declared to be quite well and may happen to go out to supper and take a little more alcohol than usual. This may affect the urethra, which is still irritable, and the consequence may be retention of urine of the spasmodic form, cases of which are very often seen by house surgeons at hospitals on Saturday nights. The fact is that the half-holiday on Saturday seems in some way to cause many people to take more liquor than is safe for them to carry; and in the case of a man with an irritable urethra, where spasm has been set up, by midnight on Saturday he is suffering from a condition of retention of urine which ultimately becomes extremely painful. That is the kind of patient who comes to the hospital in the middle of the night, or rings you up, if a practitioner, to be relieved. In such a case there is no doubt that the simplest and best plan for all parties concerned is to slip a catheter into the urethra, doing as little damage as possible. The kind of instrument to use is one of the soft indiarubber catheters generally known as a Jacques catheter, which you can introduce well oiled without giving pain. *Now supposing* that you have got the catheter in to a certain distance and yet you find that it will not go into the bladder, if you will take an old-fashioned stylet and pass it down the catheter it will give you command of the instrument which in all probability will then go into the bladder and you will be able to draw the urine off, and you can give the patient a little opium and send him away. A better instrument, perhaps, is the old fashioned English catheter with a broad end. If you take the stylet out and push the instrument steadily down, as a general rule you will find that your attempt will be successful, but failing with that method you should replace the stylet and then it is probable that you will reach the bladder. If, however, you do not manage that, the best thing to do then is to put the patient under the influence of chloroform, when the spasm at once relaxes and the instrument is able to reach the bladder.

It may not, however, be convenient for a medical man to pass a catheter. He may be driving round his district on a Sunday morning, for instance, and he may be called into a cottage to attend a man who has been drunk overnight and whose bladder is distended. The practitioner may not have a catheter with him, but he probably has his midwifery case with some opium, and if the man has some laudanum given him and directions are left as to hot fomentations to the lower part of the abdomen, in the course of one or two hours the urine may begin to pass, and if it does not the *medical man would have left word that he should be sent for.*

It used to be said formerly that if there was any difficulty in passing a catheter it should be attempted to be passed while the patient was in a hot bath, but the method involves certain inconveniences. In the first place, it is not always an easy thing to get hot water, especially in the middle of the night, and then you must remember that the surgeon has to bend over the bath to manipulate the catheter, with the result that the heat makes his face and head sweat profusely. As a matter of fact, there is no advantage in the hot bath when you can use chloroform.

Another condition of retention is the much more serious one when the patient knows and tells you that he has had a stricture for years, that he has had repeated gonorrhœas, has been under various treatments, and has been dilated more than once, perhaps to full size. You may be quite sure also that his surgeon has warned him that he ought always to have a catheter passed at least once a month. The first Sunday in the month is the rule which I generally insist upon, because you must have a fixed day and Sunday is a day of leisure. If a patient will only pass a catheter on the first Sunday in the month he will not have any difficulty in using the instrument, but if he misses for three months he will find a certain amount of difficulty and probably will have to go under his medical man again.

In regard to treatment, in the first place a proper attempt should be made to pass a catheter, and you will get a great deal of advantage from using the modern French olivary catheters. They are so small that only a few drops of urine can pass through, but if you quietly sit down by the patient—and I advise you to put the patient into a recumbent position—and make up your mind to work quietly with the catheter, turning it round so that it acquires a twisting movement, you will as a rule find that you can somehow reach the bladder along the urethra. Of course I need hardly remind you that you should begin with a moderately large catheter and gradually reduce the size. In the bulk of these cases the catheter is stopped in front of the triangular ligament and if you have begun with an English No. 3 or No. 6 of the French scale and have worked your way down in the sizes gradually until you have come to an instrument which will pass the constriction, let me advise you to tie it in. The effect of tying in a small catheter for 24 hours is that it dilates the stricture, which will further relax and on the next day you will find that it will take a larger-sized catheter. Supposing, however, you are unable to get any instrument through, you must relieve the patient and get the urine out of the bladder, and for this reason—these patients suffer much from violent spasms, and you will see a man with his hands clasped over his bladder bending forward in great pain, and if untreated he may burst his urethra. The bladder itself very rarely gives way, but what will rupture is the urethra behind the stricture, and then the patient runs the risks and dangers attending extravasation of urine.

After having tried elastic instruments, if still unsuccessful you must fall back upon silver *instruments. I know that* in the present day silver instruments are not in favour, but I think that every surgeon ought to learn to pass silver instruments. I should recommend you particularly to remember how easy it is to push a silver instrument through the walls of the urethra and thereby miss the stricture altogether. What you ought to do is with great care and gentleness, and yet with firm pressure, to get the catheter through the stricture. It is not difficult to grip the urethra with the fingers and thumb of the left hand and you can then manipulate the instrument exactly in the middle line. You can feel the end of the catheter, and you proceed to thread it, so to speak, through the stricture, and when that is done you can bring the end down gently and the instrument passes into the bladder and the urine will flow. Again, in such a case as this you should tie the instrument in for 24 hours. Supposing, however, as is very probable, that someone has been attempting to pass an instrument previously and has made a false passage (you will notice that false passages are always ascribed to the previous operator)—supposing someone has made a false passage, you will find that the catheter is very apt to slip into it. Having, however, got through the stricture in front of the triangular ligament you can keep the catheter in the right line by placing the left forefinger in the rectum, and by pressing upward and getting the catheter on the top of the finger you can guide it steadily on in the middle line into the bladder. It is all nonsense to say that you cannot be quite certain whether the instrument is in the bladder or not; you know when it has entered the bladder by the flowing of the urine.

With a certain amount of skill I think that most cases of stricture ought to yield to the use of the catheter, provided the surgeon is persevering and the patient lies quiet. This the patient may do, but patients are not always quiet, and therefore it is very convenient in these cases where there is any such difficulty to put the patient under an anæsthetic. The advantages of the use of an anæsthetic are that it keeps the patient perfectly quiet and also relieves muscular strain—for while he is conscious he cannot help straining—and the surgeon is thus enabled to slip the catheter into the bladder. Still, cases do occur where even the best surgeons may fail to pass a catheter, and then in the case of a man in such a parlous condition as that of retention of urine with an impermeable stricture something must be done, otherwise you may have extravasation of the urine. In the old days the advice given under these circumstances was to tap the bladder per rectum with a curved trocar and cannula. The finger was introduced into the rectum, the cannula was slipped over that and the trocar was thrust into the bladder behind the prostate and the cannula tied in.

Another way of meeting the difficulty was to puncture above the pubes. That, however, has fallen into disuse because for the last 30 years we have had the aspirator for the purpose, and there is nothing, so far as I know, safer than aspirating the bladder above the pubes in those cases where you cannot get a catheter to pass. All you have to do is to shave a portion of the skin and then clean it up. You should choose one of the fine straight needles of the aspirator and it should be plunged into the bladder in the middle line just above the pubes. The peritoneum will have been pushed up by the bladder and there is no risk of wounding the peritoneum.

Aspirating the bladder above the pubes may have to be repeated and I do not know that there is any danger in repeating the operation once or twice. If done repeatedly, however, you may set up inflammatory trouble in the cellular tissue round the bladder. Some years ago one of the surgeons at St. George's Hospital read a paper deprecating the method of suprapubic aspiration because of the danger of putrid urine finding its way into the cellular tissue, but I would point out that urine is not unusually putrid in the bladder. A man's urine does not decompose for a very considerable time, and probably would not do so at all unless some organism were introduced by the passing of a dirty catheter. You may take it therefore that so long as the bladder has not been catheterised the urine will remain sweet, and no risk will be run by performing the suprapubic puncture. In the case therefore of an impermeable stricture, found to be so after all methods of catheterisation have been tried, the best treatment is to aspirate above the pubes.

Perhaps, however, the surgeon is anxious to cure the stricture at once, in which case the safest operation is Wheelhouse's. The instruments required are a straight staff with a hook at the end, a probe-pointed director, and a gorget. The operation is not often required for retention; it is more often wanted for cases where, though there is no retention, it is not possible to pass a catheter. What you do is this: the straight staff is pushed down the urethra to the stricture and a free opening in the urethra is made above the stricture. The incision is widened by forceps being put on, the hook of the staff is turned round, and the staff is then withdrawn so that its extremity acts as an upward retractor of one angle of the wound. With a probe-pointed director the stricture is then found and is brought into view; the stricture is divided by a probe-pointed bistoury and then a pointed gorget is passed along the director into the bladder, when a catheter can be passed along the whole length of the urethra and upon the gorget into that organ.

We come now to a condition of things which is often not recognised. I refer to retention of urine from atony of the bladder, that is to say, that the muscular coats of the bladder have been so weakened by continued distension that they fail to contract. I do not refer to cases of cerebral or spinal paralysis; what I mean is simply that the patient has not had the opportunity of emptying his bladder as he should have done, with the result that the bladder has become over-distended and cannot right itself. Looking back for about 40 years I can remember that the cases were more numerous then than they are now, and they often occurred in the early days of railway travelling when patients were a long time in the carriages without any convenience in the way of lavatories, such as are provided nowadays. I will tell you of a case. An elderly gentleman who was travelling from Manchester to London was unable to empty his bladder until his arrival, because he knew that the performance of this act would take him some few minutes and he did not get out at any of the intermediate stations for fear of losing the train. On his arrival at Euston he tried to empty his bladder but found that he could not do so. He therefore went home and sent for his medical attendant who came, examined him, and said: "You have caught cold and are suffering from suppression of urine, and you must take some diuretics." The patient had diuretics and within 24 hours his urine was observed to be dribbling away, the medical man remarking that that confirmed his diagnosis; but this gentleman quite failed to recognise that the urine was dribbling away because the bladder was overfilled. The ureters of that unfortunate patient became gradually distended and then the kidneys were similarly affected, with the result that the patient died. At the post-mortem examination, of course, there was the full bladder to be seen and it was recognised in what manner the patient had died. Now, gentlemen, if there is one thing more than another which you should remember it is that overflow of urine means a full bladder. An empty bladder does not discharge urine in that way, but if the urethra is fairly healthy and the bladder is full the urine will dribble away in the manner which I have described. Therefore, if a patient comes to you complaining of his urine dribbling away you must pass an instrument, and you will probably find that the bladder is full. You must also remember that after you have drawn off the urine in a case of the kind I have just mentioned you must not expect to cure your patient without further treatment. You will have to pass a catheter with all necessary precautions every six hours for some days, until the bladder gradually recovers itself. The administration of strychnine is very useful under these circumstances because it certainly helps to tone up the bladder, but if you find that the patient does not recover his power of micturition it is a good plan to use the electric current and in that way to stimulate the organ.

We next come to a disease of old age—namely, retention from enlargement of the prostate. I suppose most men who are getting on towards 70 years of age have a certain amount of enlargement of the prostate, but they do not all by any means have retention of urine; but you must remember that prostatic retention may occur in any old man, and that it is quite a mistake to suppose that the affection implies any excess on the part of the sufferer. An old gentleman may have an enlarged prostate without being troubled by it at all, and he may never have had to pass a catheter, but he may have to go out to dinner, and the common thing in dress-clothes is that the trousers are of thinner material than those usually worn. On going home he may have to wait about in a bitterly cold wind till his carriage comes up; he receives a severe chill and that may lead to congestion of his prostate, and then he finds that he is unable to pass urine. You will find that these are cases which require very careful management. You will probably be sent for late at night, and you ought to go provided with all sorts and kinds of catheters. In the first place you should try a soft india-rubber catheter which you know by the name of Jacques' catheter, and you will very often be able to slip that in without any particular difficulty. If you fail with that you can try what is known as the elbowed catheter. This instrument is made of a good length because the urethra in these cases is apt to be longer than usual. The end of the instrument is tipped up so that it shall keep along the roof of the urethra, and you must take care that the name of the maker is opposite to the turned-up end or you must make a notch to furnish you with that indication. When passing the instrument you can either have the patient standing up or in the recumbent position, personally I prefer the latter. On passing it you will find that with a little pressure it reaches the bladder, when the urine can be drawn off, and in that particular class of case I do not think that it is advisable to tie in the catheter. Supposing, however, that you have not got an elbowed catheter you will find that the old fashioned English catheter is very useful, and it may be used on an occasion like this with or without the stylet. If used with a stylet the end must be bent well down. After you have introduced it and it is difficult to push it further on you should withdraw the stylet, when the end of the catheter will curl upwards, and in the majority of cases the bladder can be reached. You see, therefore, that in most cases you will probably succeed with a Jacques' or with a French elbowed catheter, or with an English catheter. When you draw the urine off from the bladder you must not be surprised if it is bloody, for it will be so in all these cases, therefore it is just as well to warn the friends and the patient that the urine will be bloody beforehand and to observe that it is not from anyone's fault.

It may be that you will be called in to a case where some medical man has previously attempted to draw off the urine by the means which I have just mentioned to you. Supposing that every attempt with elastic instruments has failed I think you will do well to use a silver prostatic catheter. It is a large curved instrument and it is passed on steadily up the urethra till some obstruction is met with; a finger is then put into the rectum and the end of the instrument is tipped up, when it should pass on into the bladder easily. You will be astonished sometimes how easily a silver catheter gets past a difficult obstruction which no elastic catheter has been able to overcome.

In these cases there is, as I have said, a certain amount of hæmorrhage, but it is not serious, though it may happen in a prostatic case that you will have to deal with a considerable hæmorrhage into the bladder and large clots may form, practically filling it. That is rather a serious position. I remember being called in by a gentleman who asked my assistance under the following circumstances. He had a Member of Parliament under his care who was bleeding into the bladder, and he was completely worn out with passing catheters, so he wanted to open the bladder. I went and saw the patient and I said, "If you open that man's bladder you will kill him. If you will hold your hand for a few hours and put the patient under the influence of opium it will relieve all the spasm, the clot will break up, you may be quite sure that the urine will do that, and I advise that a catheter should be passed only night and morning." My advice was taken and the patient got perfectly well. Years went by, and it happened that the gentleman who had called me in published a paper on this subject in one of the medical journals, in which he narrated this case with considerable accuracy, alluding to the treatment as his own and not mentioning my name.

Certain treatments have been carried out for the condition of enlarged prostate, and though perhaps they may not quite come under the heading of retention, yet you must remember that a man with an enlarged prostate is more liable to retention than are other men. The first I will mention is that of prostatectomy. The late Mr. McGill of Leeds thought the operation out, and he opened the bladder above the pubes and snipped out any projecting mass of the prostate. The surgeons at Leeds took the operation up and I remember, when there was a big medical meeting there, one of the features of the gathering was a benchful of elderly men, each holding a bottle containing a portion of his prostate. The method answered very well but there was the risk of hæmorrhage and the patient was liable to septic troubles, and practically the operation has fallen into disuse. Dr. White of Philadelphia then recommended removing the testicles in cases of enlarged prostate. I think there can be no doubt that the removal of both testicles does lead to shrinking of the prostate, but it also in some cases leads to a considerable affection of the nervous system of the patient, and there has been an uncomfortable number of suicides after this operation. I only did it once myself in this hospital, and in that case the man very much improved and was able to micturate with great comfort.

The last operation I shall mention is that of Mr. Reginald Harrison, formerly of Liverpool, now of London. He finds that by taking out a piece of the vas deferens on each side he prevents any flow of the spermatic fluid into the urethra, and this leads to atrophy of the prostate, but at the same time it leaves the testicles untouched, and therefore the mental effect on the nervous system is avoided and the patient has the satisfaction of retaining his organs. In my opinion that operation seems to be the best.

Retention in the female occurs, of course, most generally in connexion with pregnancy and let me beg of you, gentlemen, although I know nothing of midwifery, not to overlook a full bladder. Examine the patient for yourselves, do not take the word of the nurse, however highly trained she may be and however many certificates she may hold. If you have the slightest doubt pass a catheter, for many of the serious accidents following parturition are due to the prolonged presence of a full bladder. If the uterus becomes retroverted or even retroflexed the bladder may be affected and retention be set up, and ordinarily there is no difficulty in passing a catheter. Under certain circumstances, however, there may be some degree of difficulty in introducing an instrument, because sometimes the urethra is so drawn away that it renders the passing of the catheter awkward, and in that case there should be no hesitation in making the necessary exposure for the instrument to be inserted.

Lastly, there is that form of retention which we meet with in young people and which is called "hysterical" retention." I suppose it really is hysterical retention, and I am referring to such a case as when a young girl at a school holds her urine a little longer than usual and then says that she cannot pass it. There is no difficulty in the treatment; the great secret is not to pass a catheter. You should leave the patient for a little while, and tell the mother or the matron to put the girl into a hot bath and exhort her to try to micturate. Then, if she will not, a jug of cold water should be suddenly thrown over her head and shoulders, and that will most certainly have the desired effect.

AN EARLY EXPERIENCE CONCERNING THE THERAPEUTIC VIRTUES OF IODIDE OF POTASSIUM IN ASTHMATIC AFFECTIONS.

BY SIR W. T. GAIRDNER, K.C.B., M.D. EDIN., F.R.S.,
LATE PROFESSOR OF MEDICINE IN THE UNIVERSITY OF GLASGOW

IT has occurred to me to send to THE LANCET the following excerpt from a volume which is about to be published by Messrs. James Maclehose and Sons in connexion with the celebration of the ninth jubilee of the University of Glasgow on June 12th and following days. Being asked to *furnish* some reminiscences—not all, or even chiefly, medical—to this volume, I was led in the course of these to recall *some* points which may have interest more particularly for medical readers, especially for my old pupils now dispersed all over the world, and whose attention may possibly be drawn to this volume by the knowledge that it contains *some personal* recollections of the days of the great migration from the old college in the High-street of Glasgow to the new educational home on Gilmorehill.

In submitting a proof of this portion of my article to my ex-colleague, Professor Stockman, I am confirmed in the impression that the facts here placed on record, although without any pretension to scientific or pharmacological importance, may have a certain significance for those who care to trace the beginning of a therapeutic use of the iodides now generally acknowledged, but not at all so in the "fifties," to which date the first experiences of Dr. Barclay are to be referred. Dr. Stockman writes to me as follows:

"It is very interesting to find that Jephson of *Leamington* should have prescribed potassium iodide *for* bronchitic asthma. I have no note and have come across no account as to where or by whom it was first employed in these cases As a student I merely heard of it in a general way, and I only learned its value in some cases from its effect on a patient of mine who brought me a renowned (in certain circles) and secret asthma cure made up and sold by a chemist in Loanhead This patient had been advised by a friend to try it, and it really practically cured him It contained nothing but 20 grains of sodium iodide in each dose, with some flavouring matters, no stramonium, no belladonna, &c There is no mention of iodine or iodides for treatment of asthma or bronchitis by Cogswell (1837) or by Boinet (1855), both of whom wrote treatises on the therapeutic uses of iodine and its compounds Their use in asthma is pretty well known now, but it would certainly do no harm to draw attention to it in the special way you intend"

"From the time when he was the minister of Currie parish, at least, Principal Barclay had been subject to severe asthmatic seizures, which [illegible]

[illegible] the medicine indicated in it had been found of very great service in Dr Barclay's asthma, but that neither of them could understand the *rationale* of the prescription This was not very wonderful, as it was one of those [illegible] to discover the *modus operandi* of any particular constituent. Yet it was a very favourable example of this particular kind of prescription, 'elegant' in its form (to use the conventional word) and, as regards its effects, quite worthy of the great reputation of the late Dr Jephson of [illegible]

emanated as a pure [illegible]
practice on account [illegible]
the house of Sir Wm [illegible]
with a number of [illegible]
rest, and general hy[illegible]
conference with the [illegible]
suggestion, but aft[illegible]
Dr Barclay theren[illegible]
person on all the se[illegible]
by any reasonable i[illegible]
not disco[illegible] the fact [illegible]

[illegible] teacher of [illegible] a new therapeutic fact, and from that time onwards I rarely omitted an opportunity of preaching iodide of potassium (as well as prescribing it) in bronchial affections, together with the [illegible] conveyed by the whole [illegible]

[illegible] unexpected as [illegible] it was during a service in the College chapel and I had seen him immediately before) but the long struggle with an ever recurring disease and with many and great personal anxieties had completely exhausted a physical constitution originally of great vigour and a mind which almost to the very last was receptive and intelligent as well as sympathetic in no ordinary degree."

In conclusion, and without further discussion, I commend these simple facts to the profession with a certain sense that they might well have been published long ago had it not been for a desire for greater completeness in setting forth what had, nevertheless, a powerful and abiding influence on my own practice at the time and since

Edinburgh.

---

[1] "Although this is not a suitable place for further discussion of this subject I may be permitted to add that the properties here attributed to the iodides were quite unrecognised in the great work of Pereira, and, so far as I can discover, were unknown to the medical profession at large at the time of the incident here referred to. It is perhaps not easy to say how far the oral teaching above referred to may have in directly influenced professional opinion, but the cardinal fact of the Rev Dr Barclay's logical analysis of Jephson's prescription has never been stated in print (so far as I know) until now"

DEVON MEDICAL CHARITIES —The late Mrs E Taylor of Exeter bequeathed £1000 to the Devon and Exeter Hospital, £100 to the West of England Eye Infirmary, and £100 to the Exeter Dispensary

THE LATE PROFESSOR ALFRED HUGHES.—Mrs Hughes, the widow of the late Professor A Hughes, has contributed £1000 towards the endowment of the Alfred Hughes Anatomical Museum at University College, Cardiff.

RAT PLAGUE.

A PRELIMINARY COMMUNICATION ON AN OUTBREAK OF DISEASE IN RATS AT CAPE TOWN.

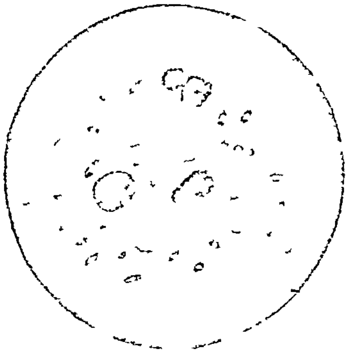
BY ALEXANDER EDINGTON, M D., F.R S EDIN ,
DIRECTOR OF THE COLONIAL BACTERIOLOGICAL INSTITUTE, CAPE COLONY

ON Feb 5th I arrived from England at Cape Town, *en route* to Port Elizabeth. At Cape Town I was informed by the Honourable the Colonial Secretary that it had been reported to him that rats were dying in great numbers from bubonic plague. He accordingly thought proper to detain me at Cape Town in order to investigate the matter. Accounts from reliable persons went to show that rats had been dying in the south arm of the docks. Instructions were therefore issued to the police and others to procure for me specimens of infected rats either dead or alive. During the following six days, however, no rats were found and I was therefore forced to report that, so far, no evidence had been brought forward to show that rats were dying from plague On the following day, however, a rat was found in the south arm which had just died and it was forwarded to me, while at the same time authority was given to me to proceed to the isolated station to which certain persons who were believed to be suffering from bubonic plague had been sent On proceeding to the latter place I found 12 persons had been admitted, most of whom had very well-marked buboes either in the femoral or axillary regions I opened into most of the buboes by means of a sterilised hypodermic syringe and in the material thus collected I was able to demonstrate the presence of the bacillus of bubonic plague in most instances. Cultivation experiments were also successfully carried out and since that date I have produced the disease by inoculation of the cultures in guinea-pigs and rabbits It is, however, in connexion with the disease in rats that this communication has been made.

The rat sent to me as having recently died in the south arm of the docks was carefully examined. At the post-mortem examination which was made with the assistance of my colleague Mr. Duncan Hutcheon, M R C V S , the chief of the Colonial Veterinary Department, the following conditions were seen. The animal was well nourished No fluid or exudation was seen in connexion with either the mouth, the eyes, or the nose. No subcutaneous hæmorrhages were noticed There was an abundance of clear, yellow serum in the pleural cavity and the pericardium was filled with a similar fluid The lungs were quite normal The blood in the heart was still fluid and no pathological changes were observed in the heart. The peritoneum was normal The liver was congested but showed no other change The spleen was normal in size, colour, and consistence. The adrenals were enlarged and very pale in colour. No enlarged glands were found. The blood in the veins was fluid On making a microscopic examination of the heart blood, axillary blood, and the spleen and liver juice, I found enormous numbers of bacteria Their form was oval and frequently they were joined as diplobacteria In size the longest segments, which, like the shorter forms, always had rounded ends, were 3μ in length and 1 5μ in breadth The diplobacterial forms measured 4μ in length and 1 2μ in breadth, while the smaller single oval forms measured 1 5μ in length and 1μ in breadth. In preparations from the spleen which were stained by methyl violet simultaneously with preparations made from the buboes of the patients affected with plague, while in the latter the bacteria always showed well-marked bi-polar staining the rat bacteria did not show this reaction. Fig 1 shows the form of the plague microbes as seen in the buboes, while Fig 2 shows the forms of the rat bacterium Fig 3 shows a primary culture of the plague bacilli, while Fig 4 shows a primary culture of the rat bacterium. These cultures were made, the rat on the evening of Feb. 11th and the plague microbe on the morning of Feb 12th The same batch of agar agar was used and the examinations were made two days later The culture of the rat microbe was much more profuse than that obtained from patients suffering from the plague In the latter case only a few isolated colonies grew, while in the former the spleen gave an almost confluent mass of growth and the blood yielded discrete colonies.

The primary culture of the rat microbe presented the most remarkable forms: some were diplococci or diplo-bacteria, others formed single and longer segments, while others formed large cells the somewhat spherical form of which was irregular in conformation, staining affinities, and size. The latter observation, taken in conjunction with the results of microscopical examination of the organs and blood of the rat, caused me to declare, pending further experiments, that the disease in the rats was not identical with bubonic plague. On culture the rat microbe does not present any characteristic which would sufficiently distinguish it from bubonic plague. Moreover, in buttered bouillon it also forms stalactite growths. Inoculations of the bacilli obtained from the patients afflicted with Cape plague on litmus agar showed an acid reaction after eight days but the rat bacterium failed to show this.

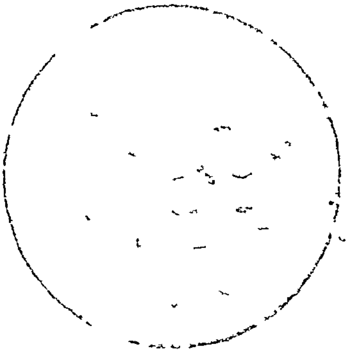
FIG. 1



Pus from bubo of a Cape Town case of plague

After journeying to Grahamstown I proceeded to carry out experimental inoculations in animals with the cultures derived from the rat. In my inoculation experiments the following procedure was carried out for the purpose of preparing material for inoculation. A tube of alkaline bouillon was inoculated with a trace of an agar culture by means of a platinum needle, and after 24 hours' cultivation from five to 10 drops were used to inoculate animals by subcutaneous injection. Such a bouillon tube thus inoculated shows only a very slight turbidity after shaking and the quantity of the bacteria contained in five or 10 drops is, therefore, not large. On March 1st two guinea-pigs, Nos. 1 and 2, were each inoculated with 10 drops of a 24 hours' old bouillon culture. On the following day both seemed well, but on March 3rd both were very sick and No. 1 died on that day. The post-mortem examination was made almost at the moment of death. The eyes were bright and had a very slight watery discharge seen at the inner canthi. Under the skin of the right foreleg was found a small gland two millimetres in length and one millimetre in breadth. It was semi-transparent and seemed filled with a watery fluid. Almost the whole of the subcutaneous tissue, specially that on the ventral surface of the body, was occupied by a pale gelatinous œdema. On the left side was found a small area 10 millimetres in diameter, slightly hæmorrhagic in character. In the left groin two glands were found, very small in size, which were also œdematous, and when cut emitted a clear fluid. The site of inoculation was enormously œdematous and the track of the needle was defined by a slight extravasation of blood. The œdema around and beneath this was absolutely clear and coagulated, being about six millimetres in thickness. This area of clear œdema was one and a half inches in length. The spleen was very slightly enlarged, being about 21 millimetres in length and 10 millimetres in breadth and two millimetres in its thickest part. In consistence it was firm and no abnormality otherwise was detected. One small gland was also found in the abdomen which was almost transparent. The liver was slightly congested, otherwise normal. Cultures made from the blood of the heart and the juice of the liver and the spleen allowed of my recovering the bacterium again in a state of purity. Examinations of the spleen pulp revealed innumerable bacteria. The whole looked like a pure culture

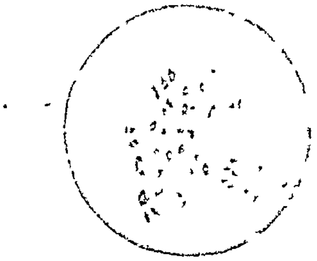
FIG 2.



Juice from spleen of rat dead from rat plague

On March 4th Guinea-pig No. 2 died. The post-mortem examination revealed similar conditions to that found in Guinea-pig No. 1, but certain additional features were also to be noticed. There was a small amount of fluid in the pericardium. The spleen was enlarged and covered all over with small white points similar to the condition which is found in guinea-pigs which have been inoculated with bubonic plague bacilli. One enlarged gland was found in the area of inoculation which was hyperæmic and opaque. Such glands as were found in other situations were semi-transparent as in the former cases.

FIG. 3.



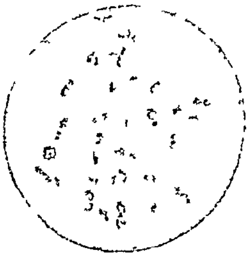
Primary culture from bubo of a Cape Town case of plague

On March 4th a guinea-pig (No. 3) was inoculated with 10 drops of a 24 hours' old bouillon culture. On March 8th it died, and the post-mortem examination showed conditions similar to those found in Guinea-pig No. 2.

On March 5th a baboon was inoculated with 10 drops of the same culture as was used to inoculate Guinea-pig No. 3. The inoculation was made in the forearm. No swelling formed at the site of inoculation and no bubo formed in the axilla. It was never sick and to-day, three weeks later, it is in perfect health.

On March 7th two rabbits (Nos. 1 and 2) were each inoculated with 10 drops of a bouillon culture and a guinea-pig (No. 4) was inoculated with the same material and dose as control. On March 12th Guinea-pig No. 4 died and the post-mortem examination revealed similar lesions to those seen in Guinea-pigs Nos. 2 and 3. As the rabbits never showed the slightest signs of sickness they were re-inoculated on March 19th with 10 drops of a 24-hours bouillon culture of the bubonic plague bacilli which I had isolated from one of the Cape Town cases, and at the same time I inoculated one guinea-pig (No. 6) with the same dose for the purpose of control to this experiment. As this latter animal, however, struggled at the moment of inoculation a portion of

FIG. 4.



Culture from spleen of rat dead from rat plague. (Figs. 1 to 4, Zeiss, 2 mm. ap and ocular 8).

the material was ejected from the inoculation wound, so [illegible] must have been smaller than [illegible] first instance. On March 24th [illegible] a great sanguineous œdema at the site of inoculation involving several glands. There was some congestion of the larger bowel. The liver was enlarged, congested, and showed a number of small white points which were irregularly scattered here and there over it. These points were irregular in size, never exceeding a millimetre in diameter, many being smaller. The spleen was enlarged and discoloured, portions being reddish and parts, especially towards one end, greenish in colour. Several enlarged and hyperæmic glands were discovered. The lungs showed inflammation in patches and a small amount of fluid was found in the pericardium. Pure cultures of the bacilli were obtained from the spleen and liver On the 25th Rabbit No. 2 died. The post-mortem examination revealed similar conditions as in Rabbit No. 1. The spleen showed a similar discolouration, while the white points in the liver were much more numerous. Cultures of the plague bacilli were also obtained from the spleen and blood in this case.

On March 26th Guinea pig No 4 (control experiment) died. A great tumour was found at the site of the inoculation of a hæmorrhagic character involving several glands. The glands of the opposite side were also enlarged. A sanguineous effusion surrounded the site of inoculation and extended over the abdomen. The lungs were affected with broncho-pneumonia and there were numerous areas of actual necrosis. Some fluid was found in the pericardium, but small in amount The liver was enlarged, congested, and had some small white points studded over it. These ranged in size from a pin-point to that of a pin-head. The spleen was enlarged and absolutely studded over its surface and throughout its substance with white points. On March 20th two rabbits (Nos. 3 and 4) and one guinea-pig (No. 7) were each inoculated with 10 drops of a 24 hours' old bouillon culture of the rat bacterium which had been passed through a guinea-pig. On March 25th the guinea pig died. The lesions in this case were very well marked and of the characters seen in the former cases of guinea pigs inoculated with this microbe The spleen was enormously enlarged. The lungs were slightly inflamed in patches On March 26th Rabbit No 3 died from causes which could not be ascertained. The post-mortem examination was kindly made by Dr. W. Ramsay Smith, the President of the Central Board of Health of South Australia, and Mr. J. Desmond, the Government veterinary surgeon of the same State. I was very pleased to have the assistance of these gentlemen, since they have had in Australia a rather extended experience in regard to the pathology and bacteriology of plague. The site of inoculation was occupied by a dry abscess the pus of which was tough and tenacious. All the organs were healthy except the liver, which was affected by animal parasites. Microscopic examination failed to detect any bacteria at all and tubes of agar which were inoculated from the liver, spleen, and blood remained sterile.

On March 28th I killed the remaining rabbit. Here, as in the former case, the site of inoculation was occupied by an abscess the pus of which was equally tough and tenacious. The lungs were affected by numerous hydatids; otherwise every organ in the body was quite healthy.

On March 26th two pigeons were each inoculated with five drops of a 12 hours' old bouillon culture of the rat microbe. Unfortunately while the inoculation was being made in the second pigeon the needle pierced the skin at the farther point and thus almost the whole of the fluid passed out among the feathers and but a small dose could have been left under the skin. The point selected for inoculation was the front of the chest between the delicate skin and the pectoral muscles. On March 31st Pigeon No. 1 died. At the post mortem examination a tumour was found between the thin integument and the muscular tissue below, and had also infiltrated the muscular substance itself. The heart was absolutely empty in the ventricles and only a trace of blood was found in the right auricle. The liver was very deeply congested. No other abnormality was detected. Examination of the blood and of the juice of the liver showed innumerable bacteria which, in the case of the liver, showed extremely well-marked bi-polar staining. Pigeon No. 2 died on the afternoon of April 1st. The post-mortem examination revealed almost identical lesions. Cultures made on agar from the blood and liver juice in both these cases gave plentiful and absolutely pure cultures of the rat microbe

Since, therefore, we have in the rat a disease which is communicable to guinea-pigs but not to rabbits, and to which rabbits are also refractory even after it has been passed through the guinea-pig; and since, moreover, inoculation of the rabbit with this rat bacterium in its virulent form gives no protection against a subsequent inoculation with bubonic plague, it seems clearly proved that this rat plague cannot be bubonic plague. The peculiar susceptibility of pigeons to the rat disease also indicates the difference between that malady and bubonic plague. In future steps will have to be taken in case of rats being affected with a disease simulating plague to inoculate other animals than guinea-pigs. My experiments show that the rabbit is probably the best animal to use in conjunction with guinea-pigs.

ALCOHOL AND ARSENIC IN THE ETIOLOGY OF ALCOHOLIC NEURITIS.

BY E. FARQUHAR BUZZARD, M.B., M.R.C.P. LOND.,
REGISTRAR TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

THE recent epidemic of arsenical neuritis amongst the beer drinkers of the northern and midland counties has led to the discussion of several interesting points in relation to peripheral neuritis in general and that form which is the result of alcoholism in particular. The word "alcoholism" is used advisedly, for we find that medical authorities are by no means agreed as to what particular constituent of alcoholic beverages is responsible for the lesions in the peripheral nerves of their consumers.

Among the most notable opinions that have recently been put forward and emphasised by eminent medical men are (1) that ethyl alcohol *per se* cannot produce neuritis; and (2) that "alcoholic neuritis" only occurs in beer-drinkers and not in pure spirit-drinkers. It has, moreover, been widely suggested (3) that alcoholic neuritis is really a misnomer and that the causal factor in those cases to which we have been accustomed to apply the name may yet be found in arsenic acting in inconsiderable doses. The first of these three theories—the one which denies to ethyl alcohol a selective pathological action on the peripheral neurons—is difficult to prove or to disprove. The second and third theories may reasonably be expected to stand or fall under the test of clinical experience and such other tests as experimental investigation may suggest.

With a view to elucidating the facts which clinical observation in a large number of cases can disclose the author of this paper has conducted a careful investigation of the notes on 120 of the most recent cases of "alcoholic" neuritis which are to be found in the case-books at the National Hospital for the Paralysed and Epileptic, Queen-square, London. The above number includes only those cases in which there seems to be no reasonable doubt that immoderate drinking was, at any rate, a possible etiological factor and does not include those in which some other toxic agent had been shown to be present, either alone or in conjunction with alcoholism. The cases occurred during the last 12 years and in that time about 20 other cases of multiple neuritis were treated in the hospital in which alcoholism was a possible but not a reliable cause. If we take all the cases of multiple neuritis for the period they can be classified thus to show their relative numerical strength.

	Cases.		Cases.
Alcohol	120	Post-influenzal	3
Alcohol (doubtful)	20	Lead	21
Alcohol and marked tuberculosis	7	Malaria	3
Alcohol and septicæmia ...	2	Arsenic	2
Septicæmia alone	4	Post-typhoid	1
Post-diphtheritic	34	Diabetic	5
		Unknown cause	5

In the study of these notes especial attention has been paid to the following points: (1) age; (2) sex; (3) habits in reference to alcohol; (4) changes of a nutritional, vaso-motor, or pigmentary nature in the skin, hairs, or nails; and (5) the result of treatment with arsenical drugs.

1 and 2. *Age and sex of the patients.*—These two points may be briefly dismissed. Among 120 patients there were

96 females and 24 males. The average age of the males was 42 8 years. The average age of the females was 38 5 years.

3. *Habits of the patients in reference to alcohol.*—In regard to this matter the notes are, on the whole, satisfactorily complete, and in quite a large proportion evidence has to both the quality and the quantity of drink taken has been obtained either from the sufferers themselves or from friends and relatives. It cannot be said that the story told by the former always tallied with the "friendly" version, but, taking the large number of cases in question, considerable value attaches to the statements thus obtained. I have classified the results of this inquiry into habits under as few headings as is possible, with a due regard to accuracy, in the following manner:—

	Cases.
Spirits only (quantities from half a pint to two bottles a day) ...	29
Spirits predominant (other forms admitted in moderation)	11
Spirits only, and in moderation	1
Spirits and wine in excess	3
Beer only and in excess	1
Beer predominant	1
Beer only and in moderation	3
Beer and wine in excess	1
Beer and spirits in excess	30
Beer, spirits, and wine in large quantities	3
Wine (port and sherry) in excess and only	1
Stout in moderation admitted	1
Stout and spirits	4
No mention of habits	11
Alcoholic excess without specification of form	20
Total	120

In the first class, that which contains the consumers of large quantities of spirits only, there are a considerable number in which, from the evidence of friends and patients alike, there can be no doubt that brandy, whisky, or gin was the sole stimulant consumed. Others base their claims to be included in this class on the evidence either of their friends or of their own admissions. It has been urged by some physicians that if the question and inquiry are only pushed far enough beer will always be found to be associated even with large quantities of spirits in the daily diet of these patients. It is scarcely credible, however, that a man or a woman who will unblushingly admit to consuming two bottles of brandy a day should display any bashful coyness in reference to an extra gallon or so of ale. On the other hand, out of 89 cases in which habits are noted there is but one in which there can be no reasonable doubt that beer alone, and beer in large quantities, was the only form of alcoholic liquor taken. As one would expect in the class from which hospital patients are drawn, it is among the mixed beer- and spirit-drinkers that the most numerous victims of this disease, are to be found and quite a large proportion of those who come under this head are connected with the liquor trade either as barmaids, publicans, or the wives of publicans. The figures given above undoubtedly point to the conclusion that in London, where there is a large beer-drinking community, it is among the consumers of pure spirits, either alone or in conjunction with beer, that the clinical picture of alcoholic neuritis is most frequently found.

4. *Changes of a nutritional, vaso-motor, or pigmentary nature in the skin, hair, or nails.*—In 57 of the 120 cases no special reference was made to the condition of the skin or of its appendages, and these are therefore valueless for the present purpose. In 23 cases it is specially noted that no skin changes were to be found. In 40 cases vaso-motor, trophic, or pigmentary abnormalities are described and their nature presents an interesting and useful study when brought into comparison with those changes which are known to be a consequence of arsenical poisoning. Under the head of trophic disturbance it is to be remarked that the skin on the hands and feet is generally described as (*a*) thin and glossy or shiny, or (*b*) soft, soapy, or boiled in appearance. Along with the thin shiny skin which is particularly observed on the digits is found striation, brittleness, or a reeded condition of the nails. Profuse perspiration, limited to the extremities, generally accompanies, and probably accounts for, the soft, soapy condition of the skin, which has been likened to that found in washerwomen's hands. The colour of the skin on the hands and feet is usually described as white, but in some cases there have been purple or red patches, generally over joints in which adhesions are present or, in one case, over the palmar surface of the phalanges. In reference to pigmentation one case, that of a mixed beer- and spirit drinker, is found in which the skin is described as pigmented in the groins and over the abdomen. In another there were some pigmented scars on the shins, but with these exceptions pigmentation is conspicuous by its absence. Vaso-motor changes, apart from [illegible] not frequently noted, but in a few case [illegible] ance of the lower extremities, with or [illegible] ankles, appears to be a feature.

In considering the above observations the fact is at once evident that the whole of the conditions mentioned with two exceptions (one of trunk pigmentation and one of keratosis of the plantar surfaces) are those which can be, and frequently are, met with not only in all forms of peripheral neuritis but also in other diseases in which the lower neurons are affected, such as progressive muscular atrophy, amyotrophic lateral sclerosis, and the like. These secondary skin changes are, indeed, the outward and visible signs of a disturbed nutrition due to an abeyance or alteration of the trophic function of the peripheral neurons and are quite distinct from the primary cutaneous changes in arsenical poisoning where the toxin at work exercises a specific influence on the cutis and cutaneous appendages. It is true that in the latter class of cases one may, and does, find the signs of secondary cutaneous atrophy present in addition, since arsenic shares with other toxic substances the power of producing pathological changes in the nerves themselves.

Two other notable features of my series of cases deserve a word or two in this relation. There is no mention of a single case of herpes or of erythromelalgia in the 120 cases. The absence of these two nervous phenomena is of particular importance because neither would be likely to escape observation in the hospital under consideration, where both have gained a large amount of attention. Yet it is said that amongst arsenical beer-drinkers both these physical signs are by no means uncommon. The non-occurrence of herpes, at any rate, cannot be explained on the ground that the dose of arsenic is insufficient, for I have on several occasions noted a crop of herpes following on small doses of Fowler's solution administered over a very short space of time, and the causal or predisposing relation of that metal to herpes has received general acceptance and confirmation since Mr. Jonathan Hutchinson first brought it forward. In this connexion it is interesting to note that out of a very limited number of cases of diabetic neuritis which have come under my observation I have on two occasions met with herpes zoster. Arsenical and diabetic neuritis resemble each other, moreover, in the severe character of the sensory phenomena; in both diseases spontaneous and continuous pain, apart from muscular tenderness in the affected limbs, is a much more marked feature than is commonly the case in alcoholic neuritis.

The term "erythromelalgia" properly refers to a symptom-complex in which pain, local heat, and flushing, all aggravated or initiated by a dependent position of the affected part, are pathognomonic, and is distinct from the phenomenon of ordinary vaso-motor palsy, to which, unfortunately, the name has been sometimes loosely applied. As far as I can ascertain no true instance of this condition has been observed in a case of alcoholic neuritis, or indeed of any other form of multiple neuritis, at Queen-square.

5. *The result of treatment with arsenical drugs.*—More than one physician at the hospital has from time to time treated his cases of alcoholic neuritis with doses of Fowler's solution, and the course of the disease in these patients whilst under the influence of this drug cannot be without interest in view of the part which arsenic may or may not play in the production of this morbid condition. Twenty-four cases were treated with arsenical solution in doses of two, three, or four minims given three times a day. In 17 of these the amount taken was nine minims and in four others 12 minims per diem. The period over which the drug was exhibited varied from one week to eight months and in the majority of cases it was from three to five months. The results obtained in the whole series of 120 cases may be thus compared with those obtained in the 24 where arsenious anhydride was administered:—

—	Cured.	Greatly improved.	Improved.	In statu quo.	Deceased.
Arsenious anhydride 0 06 to 0 12 gr. daily ..	3	12	9	0	0
No arsenical drug given ..	31	33	36	7	13

I would not for a moment contend that the favourable results obtained in the first part of the table were due to the administration of this drug; on the contrary, it must be allowed that Fowler's solution would, in all probability, only be used when the patients had passed the most acute stage in the disease. At the same time it is a striking fact that none of those cases were unfavourably influenced by the exhibition of arsenic and that at least two-thirds of them left the hospital either cured or well on the road to recovery.

It will probably be admitted by most physicians that the essential condition for recovery from this form of peripheral neuritis is only attained when all access to alcoholic stimulants is prevented. If arsenic be the toxic constituent of those stimulants one would not expect the cases, when the alcohol is withheld and the toxin administered in another medium, to run an invariably favourable course. This, however, has certainly been the case in my series and as far as clinical facts permit any conclusion to be drawn they must weigh heavily in the balance against the arsenical theory in the etiology of this disease.

Whether arsenic or alcohol is the cause of this disease there is no doubt that only a very small percentage of persons who, on account of their habits, are exposed to the risk of peripheral neuritis ever show any symptoms of the condition. Probably the incidence of the morbid process can be best accounted for by a special individual susceptibility to the poison, and, if it be assumed that arsenic is the poison at work, all cases of "alcoholic" neuritis should occur in persons susceptible to that mineral. On this assumption one would expect even the small doses administered for therapeutical purposes to be sufficient to prevent or, at any rate, to retard, the recovery of sufferers from this particular form of neuritis. That this expectation is not borne out by clinical experience leads to the conclusion that arsenic is not the chief etiological factor in alcoholic neuritis.

Another point of clinical interest is the absence of any necessary association between arsenical pigmentation and arsenical neuritis, and in the National Hospital for the Paralysed and Epileptic is afforded the opportunity of seeing a considerable number of patients who have been taking arsenic medicinally over long periods of time. Many of these present more or less pigmentation, but only two cases of peripheral neuritis, undoubtedly due to arsenic, have been observed in 12 years. Only a few days ago I stripped a patient who had been taking arsenical solution, to the amount of nine minims a day, fairly regularly for seven years in conjunction with bromide of potassium. The whole of the neck, the trunk, and the proximal parts of the limbs were covered with a typical arsenical pigmentation of a mottled sepia colour. No signs of cutaneous trophic changes or of peripheral neuritis were present. Still more recently I examined a man who had been taking six minims of the same drug daily for nine months. Eight months after he had ceased to take any arsenic he presented a similar condition of pigmentation in a less decided shade. Such cases represent the results of drug accumulation in persons whose nervous systems are not especially susceptible to the toxic properties of this metal. It would be interesting to know whether such cases of pigmentation are to be met with amongst heavy beer-drinkers in London who have not fallen victims to peripheral neuritis.

In recounting the results of my investigations I have purposely avoided reference to any of the clinical phenomena of alcoholic neuritis which do not help to elucidate the particular questions at issue.

One or two points may, however, have some indirect interest in this connexion. The absence of wasting and the presence of a peculiar hard condition of the calf muscles, accompanied by tenderness on pressure, has been a noted feature in one or two cases. This has been so only in mild forms of the disease and when the motor difficulty has been one rather of unsteady gait than of great paresis. Paralysis of the diaphragm has been of frequent occurrence in the fatal cases, but is not unknown in those which have recovered. Difficulty in swallowing has been recorded in a few instances. The loss of memory for time and place has been very general and, in the more severe cases, is a condition from which there is very little hope of recovery even when the activity of the limbs is restored. The presence of ocular nystagmoid movements on extreme lateral deviation and amenorrhœa are not infrequent features and are well known to most observers.

A summary of the evidence which I have obtained leads me to think that, in London at any rate, (1) alcoholic neuritis is more often found in the sequel of spirit-drinking than in other forms of alcoholism; and (2) that clinical evidence is antagonistic to the idea that arsenic is the cause of alcoholic neuritis.

It has frequently been argued that spirits cannot produce neuritis because the latter disease is uncommon in Scotland, but, as far as I am aware, no modern statistics on this point have been made. I am strongly of the opinion that a numerical comparison of cases of alcoholic neuritis with the total population in Edinburgh, Glasgow, and London would throw an important light on this line of argument.

In conclusion, I have to thank the members of the medical staff at the National Hospital for the Paralysed and Epileptic for their kind permission to make use of their case-books for the purpose of this investigation.

Harley-street, W.

AN EXPLANATION OF THE VULNERABILITY OF THE APICES IN TUBERCULOSIS OF THE LUNGS.

By E. H. COLBECK, B.A., M.D. CANTAB., M.R.C.P. LOND.,

AND

ERIC PRITCHARD, M.A., M.D. OXON., M.R.C.P. LOND.

IT has been generally admitted since the time of Laennec and Louis that the apices constitute the most vulnerable portions of the lungs when these organs become the seat of tuberculosis. Statistics collected from divers sources bearing on this subject vary somewhat, but they show that from 60 to 80 per cent. of the cases of pulmonary tuberculosis commence in the apices of the lungs, the initial lesion being rather more common on the right than on the left side, in the proportion of slightly less than three to two. Now, while there is a practical unanimity of opinion as regards the primary site of the disease in pulmonary tuberculosis, there is no sort of agreement among observers with respect to the cause of the peculiar vulnerability of the apices. Indeed, it may almost be said that our knowledge of the exact conditions which determine the special proclivity of the apices to tuberculosis is inversely proportional to the number of theories that have been advanced to elucidate them. Nevertheless, it is by no means improbable that some of the attempts which have been made to solve the problem contain at least the germs of the true explanation of the cause of the phenomenon under consideration, and for this reason, if for no other, it becomes necessary to enumerate and to briefly review the more important theories that have been advanced.

The view that has probably met with the widest acceptance attributes the apical site of the lesion to the comparative rigidity and fixity of the upper portion of the chest, whereby the movements of the contained lung are considerably curtailed. It has, moreover, been pointed out that sedentary occupations and certain forms of manual labour, notably digging, ploughing, &c., by tending to force the shoulders forward, would still further hamper the movements of the upper portion of the chest and hence of the lung. The vulnerability of the apices is attributed under these conditions to diminished functional activity and consequently lessened power of resistance to the tubercle bacillus, which may therefore be able to effect a lodgment in this portion of the lung. While it cannot be seriously disputed that the range of movement of the upper portion of the chest is less than that of the lower parts of this structure, it is by no means proved that *relatively* the expansion and mobility of the contained lung are not as great in the former as in the latter situation. Indeed, it is probable, as Woods Hutchinson has pointed out, that the activity of the upper portions of the lungs has been underestimated. In any event it cannot be admitted that the theory under examination satisfactorily accounts for the peculiar constancy of the site of the apical lesion which is found from an inch to one and a half inches below the summit of the lung.

A modification of the theory which has just been considered suggests a mechanical explanation of the vulnerability of the apices. Thus in consequence of the imperfect expansion of the apices it is supposed that the air-cells in this situation more readily collapse or become choked with secretion, foreign matter, &c., and in this way the lodgment of bacilli is facilitated. In addition to the arguments already advanced the application of the dynamical laws under which air enters and leaves the lungs would be fatal to the tenability of this theory. A similar objection applies to the suggestion that the entrance of foreign matter, such as dust, bacilli, &c., is promoted by an increased patency of the bronchial tubes at the apex of the lung consequent on the comparatively fixed position of the upper portion of the thorax.

The theories based on suppositional abnormalities or imperfections of the circulatory conditions at the apex of the lung would hardly repay detailed discussion. Woods Hutchinson has recently approached the subject from the side of comparative pathology. He argues with great cogency that the apices from the comparative morphological standpoint are the portions of the lungs which are most unstable and therefore possess least vital resistance. He also shows that it is highly probable that the upper lobe of the right lung is morphologically more unstable than that of the left, a circumstance which if substantiated would explain the relatively greater vulnerability of the right apex.

There can be no doubt that there is a great deal of force in these arguments, but we venture to think that they do not cover the whole of the ground, nor do they offer a complete and satisfactory explanation of the peculiar susceptibility of the apices of the lungs to tuberculosis, in that they do not account for the singularly constant localisation of the lesions at a point which is situated roughly from one to one and a half inches below the summit of the lung.

We should like to preface our observations by pointing out that the constancy of the site of the apical lesion suggests to us a mechanical explanation of the special vulnerability of this portion of the lung. In searching for the conditions that might permit the operation of a mechanical cause it will be observed that the apices of the lungs, unlike the rest of the pulmonic tissue, are not contained within the thorax, but project dome-like from three-quarters of an inch to one and a half inches above the border of the first rib. The coverings of the apices consist, therefore, not of the firm wall of the chest, but of fascia, muscle, and skin, which under the most favourable conditions can offer, comparatively speaking, but an imperfect support to the lung at the outlet of the thorax. Now it sometimes happens that in the course of surgical operations in the supra-clavicular fossæ the upper surface of the pleural sac is exposed so that the movements of the subjacent lung can be seen. It has been noted in cases of this kind, as Woods Hutchinson testifies from personal observation, that the range of movement of the apices of the lungs is considerable. Indeed, this observer remarks that in one operation of this kind the way the upper surface of the pleural sac plunged about with the respiratory rhythm was "little short of appalling." We would point out that under conditions of this kind the movements of the apex of the lung must be *inverted* as regards their relation to the normal respiratory rhythm, inasmuch as the apex must be sucked into the thorax during each inspiration and protruded during expiration. Under normal conditions the support afforded to the apices of the lungs during ordinary breathing by the soft parts and sternal ends of the clavicles when the supra-clavicular muscles contract is probably sufficient to permit of the inflation of the apices during inspiration. With increasingly deep inspirations the inflation of the apices becomes relatively lessened, as is shown by the rise of pitch in the percussion note obtained in the supra clavicular fossæ. If the support afforded by the soft parts is diminished the inspiratory inflation of the apices becomes correspondingly lessened, and provided the loss of support progressively increases a time must come, for the reasons already given, when the movements of the apices become inverted in their relation to the normal respiratory rhythm.

Now, if these conclusions be well founded, the question immediately arises, "Do the conditions which give rise to an inverted movement of the apices of the lungs obtain in practice and operate in the production of disease?" The answer to this question, in our opinion, is emphatically in the affirmative for reasons which we will now adduce. Among the striking features presented by the chest of the ill-developed and weakly youth and young adult, and more particularly by the so-called "phthisical chest," which is but an exaggeration of the former type, are the forward displacement of the scapulæ and shoulders, and the maldevelopment or wasted appearance of the muscles supporting and acting upon the shoulder girdle, more especially of the sterno-cleido-mastoid, trapezius and pectoralis major. We have already pointed out that the support afforded to the dome-like projections of the lungs through the superior aperture of the thorax is largely provided by the sternal ends of the clavicles, the sterno-cleido-mastoid muscles and their fascial attachments and connexions. If the acromial ends of the clavicles are carried forwards the effect is to widen the supra-clavicular fossæ and thus to diminish the support afforded by the sternal ends of these bones to the apices of the lungs. Furthermore, if at the same time the sterno-cleido-mastoid muscles are maldeveloped or have undergone wasting the normal "trap-door" action which is exercised by these muscles and the clavicles over the superior aperture of the thorax is largely minimised or removed. It will appear, therefore, that under these circumstances the conditions which lead to an inverted movement of the apices of the lungs may be fulfilled. That they are fulfilled is shown clinically by the sucking in of the supra-clavicular fossæ during inspiration and by the change in the character of the percussion note which takes place when a deep breath is taken. Thus at the end of expiration the note elicited in the supra-clavicular fossæ is resonant, while at the end of inspiration it is either absolutely dull or its resonance is very greatly impaired. We do not think that this very important and suggestive fact has received the attention it deserves at the hands of clinical observers.

One of the pathological expressions of this inversion of the normal pulmonary movements may be the deposition of tubercle at a point in the upper lobe of the lung situated about from an inch to one and a half inches below the true apex, a site that is determined by the extent of the projection of the apices above the border of the first rib. The explanation of this peculiar localisation of the primary site of the tuberculous lesion is exactly parallel with the reason which accounts for the thin line of débris, &c., which collects where two opposing currents of air or water meet. In the case under consideration it is the "neutral" territory between the opposing currents formed on the one hand by the inverted movements of the apices and on the other by the normal movements of the rest of the lung. In other words, if foreign matter, including bacilli, can collect anywhere in the lung it is at this site that the collection is most likely to take place. The tendency to the accumulation of foreign material in this situation is increased also by the fact that under the circumstances expiratory effort is likely to drive both gaseous and solid matter up into the apices. Furthermore, the tract of lung situated immediately between the portion (upper) that undergoes the inverted movement and the portion (lower) that partakes of the normal respiratory rhythm would tend to remain comparatively immobile, and therefore to display diminished functional activity and consequently lessened powers of resistance to microbic invasion.

The greater vulnerability of the right apex as compared with the left still remains to be considered. Inasmuch as the right apex commonly rises higher into the neck than the left we suspect that the increased exposure and consequently greater liability of this side to become inadequately supported is sufficient to determine the slightly more frequent deposition of tubercle.

Our conclusions, therefore, stated generally, are that the vulnerability of the apices of the lungs to tuberculosis is largely determined by an alteration in the shape of the chest in conjunction with misplacement and deficient musculature of the shoulder girdle. Woods Hutchinson who has worked at the subject from the side of comparative morphology and pathology expresses similar views. The importance of the alteration in the shape of the chest and of the abnormal condition of the shoulder girdle lies, according to our view of the matter, in the modification which these changes induce in the dynamical relations of the superior aperture of the thorax, whereby the movements of the apices become inverted in their relation to the normal respiratory rhythm. It is in the altered dynamical relations of the respiratory mechanics at the apex that we find the conditions which favour the lodgment of extraneous matter in the upper lobes of the lungs. The exact position of the site of deposit is determined largely by the distance the apex rises above the border of the first rib, inasmuch as it is this extra-thoracic portion of lung which is acted upon by the forces that give rise to the inverted movement. Since the apex rises from an inch to one and a half inches above the border of the first rib we conclude that the site of deposit will be situated from an inch to one and a half inches below the summit of the lung. This mechanical explanation of the vulnerability of the apices of the lungs to tuberculosis in the human subject is the more interesting by reason of the fact that the proclivity to tuberculous disease of the basal lobe of the lung in cattle is in all probability likewise due to mechanical causes.

The practical bearing of the theory which we have advanced is the enormous importance of developing the muscles of the shoulder girdle with the object of "pulling the chest into shape," as Woods Hutchinson so ably and graphically puts it. To this end tree climbing, ball throwing, horizontal ladder and bar exercises—indeed, any muscular manœuvre which brings into play the great pectoral muscles should be sedulously and systematically carried out. Before leaving the subject we should like to suggest that the theory which we have put forward is pertinent to explain other abnormal conditions that occur at the apex of the lung, and in this respect we would call attention to the development of emphysema in this situation.

THE SURGICAL TREATMENT OF ULCERS OF THE STOMACH

WHICH ARE OR HAVE BEEN COMPLICATED WITH SEVERE HÆMORRHAGE.

BY C. B. KEETLEY, F.R.C.S. ENG.,
SURGEON TO THE WEST LONDON HOSPITAL.

IT is of practical importance to distinguish between severe gastric hæmorrhages and slight ones. In my experience there has so far been not much difficulty in placing individual cases in one or other of these two classes. Severe hæmorrhages are such as show, either by the vomit or by the stool, that pints, if not quarts, of fluid, chiefly blood, have escaped into either the stomach or the duodenum. It seems a comparatively secondary matter whether a given case is gastric, or affects the upper three and a half inches of the duodenum, which are quite accessible during any operation that may be performed to expose the stomach. If we are satisfied that a case is one of severe hæmorrhage from a peptic ulcer, we have made the first essential step. Precise localisation, though desirable, must generally be left to be determined by the operation, if one is performed. If anyone thinks the above preliminary remarks so obvious as to be superfluous let him read the most interesting debate on Mr. Mayo Robson's recent paper at Edinburgh[1] or Dr. Byrom Bramwell's clinical lecture,[2] and he will find in these scarcely any regard paid to the distinction between severe and slight hæmorrhages.

Both severe and slight hæmorrhages have their dangers, remote in the slight cases, immediate and remote in the severe ones. Cases of slight hæmatemesis are not, however, as a rule, treated mainly for the hæmatemesis, but on account of the disease of which the blood-stained vomit is a sign. I propose now to deal with three cases of the severe class which have come under my care in the past two years, and also to refer to the case of a personal friend of mine who was not, however, attended by me but who died abroad. These four form the total of my experience since April, 1899, when my interest was first awakened in the subject by my friend, Dr. Leonard Dobson, who had already come to the conclusion that the recent, though past, occurrence of severe hæmorrhage from the stomach indicated a condition requiring surgical treatment.

CASE 1. *Gastric ulcer adherent to the diaphragm and the pancreas which formed its base. Considerable hæmorrhages, the last nearly fatal; the adhesions separated and the ulcer scraped and sutured; recovery; recurrence of pain; gastro-enterostomy; cure.*—The patient, a female, aged 20 years, was anæmic but very well nourished. She had had three attacks of rather severe hæmatemesis, two while in the West London Hospital in October, 1898. In one of the latter she vomited a pint and a half of blood. After medical treatment under Dr. F. G. D. Drewitt she went out apparently quite cured, but in spite of careful diet the gastric symptoms returned in a month. She then had another very severe hæmorrhage, and Dr. Dobson, whose patient she was, brought her to the hospital with a view to operation. Her pain was in the epigastrium and between the shoulders. There was a tender spot two inches below the xiphoid as well as marked tenderness in the left hypochondrium. The special features of the operation (April 14th, 1899) were: (1) the position of the ulcer; (2) how it was found; and (3) how it was dealt with. 1. It was near the lesser curvature and œsophageal opening on the posterior surface and was firmly adherent to the diaphragm and the upper edge of the pancreas, which formed its base, as it had completely perforated. It was circular and seven-eighths of an inch in diameter. 2. The search for it was long and difficult. External palpation of the viscus discovered nothing. An opening was made in the anterior wall and with the finger inside the first part of the duodenum and all the stomach, except the part nearest the œsophageal opening, were reached and were systematically searched. Then a speculum was used. Lastly, the part where the ulcer proved to be was brought within reach of the tip of the left index finger, by long and very gentle dragging on the posterior wall with the right finger and thumb. 3. The treatment of the ulcer now involved division of the left rectus and prolongation of the median incision upwards to give room, as well as a sufficient perpendicular opening through the omentum into the lesser cavity of the peritoneum. Gauze packing was employed. Careful separation was made of the base of the ulcer from the pancreas and diaphragm; there was an area of thickening here two or three inches in diameter. The ulcer edges were now scraped, which procedure about doubled its diameter. Three silkworm gut sutures were passed, half an inch apart, through all the coats of the stomach, in such a way that the loops were outside and the ends inside the organ. The original opening in the anterior wall was now utilised in order to tie these three sutures with the knots inside the stomach. Although half an inch apart they had such a grip on the stomach wall that they seemed to close the hole completely. However, they were now backed up by a row of Lembert's sutures of fine silkworm gut. The anterior gastric opening was then closed by Lembert's sutures. Gauze drains were left in for four days. Uninterrupted recovery followed. Nothing but hot water and a little Apollinaris or lemonade were allowed for more than a week. Solid food was not allowed for a month. The highest temperature was 99·5° F. and the lowest 97·6°.

The patient remained well for some months, returning to work in the country. She then began to be troubled with pain and tenderness in the epigastric region again. On Oct. 19th, 1900, a second laparotomy was performed. No adhesions were found, but the lesser cavity of the omentum was not opened. An anterior gastro-enterostomy was done with a Murphy's button. The result so far (June, 1901) is apparently perfect, except that no sign of the button has been found either by x rays or otherwise. The patient is following her usual daily work and she has written: "I have never felt better in my life."

It is possible that ulceration recurred in this case or that adhesions of the site of the old ulcer to the scraped surface of the diaphragm (or the pancreas) occurred and made the movements of the stomach painful. It is possible that if I had fully dilated the pylorus at the time of the first operation—i.e., to an inside circumference of four and a half inches—I might, as in Case 3 (about to be related), have been spared the necessity of a second operation. For the notes of the case I am indebted to Mr. G. F. Briggs and Mr. O. Inchley.

CASE 2. *Severe gastric hæmorrhage; rest and opium and rectal feeding; no operation; death on the twelfth day.*—The patient was a female, aged 32 years. I was asked to see her on the morning of Sept. 25th, 1899, because, after fainting no less than five times in the preceding 24 hours and passing black stools, she had vomited three or four pints of dark blood or bloody fluid on the evening before. I saw the fluid in a bowl. She had suffered from pain after taking food for a week. I sent her into the West London Hospital, intending to see her again at my usual visit the next day, but as I sent her under a physician into a medical ward, and "out of sight is out of mind," I forgot all about the case until after the poor girl was dead. According to the note of Mr. T. Wood Hill, the house physician, on Sept. 25th her motions were black. As a rule the patient was constipated, she suffered from headaches, often from faints, and was pale in colour. Her abdomen was "resonant, very rigid, extremely tender." Rectal feeding was employed and the patient was given ice to suck. One-sixth of a grain of opium was given every six hours. On the 26th the note was: "Slept well; melæna this morning; motions fluid, blackish red." On the 27th she had slept well and there was no pain in the stomach. On the 28th the pain in the stomach was very severe and the stools were large and dark. On the 29th she was "quite comfortable" On the 30th three out of seven enemata returned. There were pain in the abdomen and great weakness. The pulse was poor before the enemata. Two-minim doses of solution of strychnine, "si opus sit," were ordered. On Oct. 2nd enemata and meat suppositories were given every four hours alternately. The pain was less. The pulse was of poor volume. On the 5th the gastric pain ceased. On the morning of the 7th the patient was suddenly seized with pain. The pulse was rapid and very poor in volume. There was no sickness. At 8 P M the pulse at the wrist was imperceptible. Venous transfusion was performed, four pints of saline solution being injected into the median basilic The temperature afterwards went up suddenly to 106·8° F. and the patient died at 4 25 A M. No post-mortem examination was allowed. Brandy had been given both by the mouth and with the enemata (two ounces per 24 hours) from Sept 28th, and bismuth mixture from Oct 4th. The temperature chart is interesting. The range was between normal and one degree subnormal until the final rise.

---

[1] The Scottish Medical and Surgical Journal, March, 1901.
[2] THE LANCET, March 9th, 1901, p. 687.

I am sorry to say that I did not remember to inquire about this case until some months had elapsed, when I was grieved to hear the course which things had taken. One question which arises in this case is, Had perforation and localised peritonitis taken place? I do not think so. Dr. E. A. Saunders and I now think that the patient's life might possibly have been saved by operation, and that the second day after her admission into hospital would have been the time to choose in this case. At all events, I did no good by "trying medical treatment first" and "waiting for a recurrence of the hæmorrhage."

CASE 3 *Long history of chronic gastric trouble; severe hæmorrhages; Loreta's operation (pylorus stretched to four and a half inches internal circumference); recovery; quite well up to one year afterwards.*—The patient was a woman, aged 39 years, who had been married for 14 years and had been a widow for nine years. She had had two children. There was a tuberculous family history (husband and son). She had suffered from indigestion since childhood and from flatulence. Since her husband's death she had worked hard and had suffered more from indigestion. She had had a cough for years. Pain began from one-quarter to half an hour after taking food. Lately the pain had been more delayed and was of a less defined character—a "sinking, uneasy sensation" In the preceding March she had a severe attack, vomiting "some quarts of blood." In October she brought up more blood This patient, like the first, was also placed under my care for operation by Dr. Leonard Dobson. She took liquid and light food well after admission and improved in appearance. The operation was carried out on April 20th. The patient had been prepared for several days by purgatives and enemata. A median epigastric incision was made. The pylorus was found to be very hard and thickened. It would not admit the tip of the little finger and it felt quite rigid. No ulcer was seen or felt; but it was not thought fair to the patient to add to her risk by making a prolonged and rigid search for ulcer. A Loreta's operation was decided upon, as I had previously seen an excellent and lasting result follow this operation when performed on a similar pylorus. Through a small opening in the anterior stomach wall a three-bladed anal dilator was passed through the pylorus until the blades were wholly inside the stomach and duodenum; 37 turns of the screw, made very gradually, dilated the pylorus to an inside circumference of four and a half inches The wound in the stomach wall was closed by three sutures penetrating *all* the coats and tied with their knots inside the lumen, and by a superimposed row of 12 Lembert's sutures. Two small drains were carried obliquely from the parietal wound to near the stomach wound and they were removed in a few days Some ether sickness occurred during the night. On the 22nd the patient vomited once and on the 23rd once. On the 26th she was very hungry. There are no other notes. Convalescence was rapid and uninterrupted. She was fed for a week on beef-tea by the mouth (half an ounce every two hours, after vomiting had ceased), and peptonised milk enemata containing plasmon. A week after the operation she also took by the mouth one drachm of milk every two hours, with plasmon, one drachm to four ounces of milk, and [illegible] soda and Benger's food, and on May [illegible] She went out well on May 26th and has remained well At Christmas she wrote, "I can now take quite ordinary food and have no signs of indigestion." The notes of the case were kindly supplied by Dr. Maurice Dee.

CASE 4. *Duodenal ulcer; perforation of pancreatico-duodenal artery; hæmatemesis and melæna; no operation; death.*—A military officer, aged 40 years, was taken into hospital with a history of severe recent hæmatemesis and melæna. He had just arrived at this place (in India) after a long journey. He had fainted while walking across the room with a glass in his hand. He had only just returned from leave in England, where he had been under treatment for a pain which came on regularly about an hour after retiring to bed—i e., about the time a late dinner would be passing into the duodenum. [illegible] but a precise diagnosis was [illegible] patient was relieved by treatment. In India the liver was suspected. He was placed on a milk diet when taken into hospital, but he died the next day. Post mortem an ulcer of the duodenum was found, perforating the pancreatico-duodenal artery. There were circumstances of special difficulty attending the diagnosis and treatment of this case which progressed chiefly during the long journey from England to India. This life was one of the highest value not only to the patient's relatives but to his country For the details of the case I am indebted to my friend and old house surgeon, Mr. H. G. Wharry. In India the patient was under the care of another old house surgeon of mine, an exceedingly able and painstaking man. The patient's family are intimate friends of mine, and an old patient of mine lay in the next bed in the Indian hospital. This case was thus brought under my notice in four distinct ways

Assuming that it is right for surgery to act in cases of severe gastric hæmorrhage the first questions which arise are *when* and *how* It is natural to turn for guidance to the experience of Billroth and his assistants, the latter still living and working with enthusiasm and with brilliance comparable to those of their great master. This school founded modern gastric surgery and has had a large share in its further development. Von Miculicz of Breslau gives a gloomy account of the result of operating during the progress of acute hæmorrhage. Only two patients had recovered out of a considerable number—one of Roux's and one of his own. He himself had lost three. Mr Mayo Robson has had a successful case—that of a woman who was operated upon on July 6th, 1900. Seven bleeding points were found Two were ligatured *en masse* and the other five stopped "on exposure to air." Posterior gastro enterostomy with bone bobbin was performed. There is another successful case just reported by Dr. Brunton Angus[3] The patient was attacked by venous thrombosis in both legs about a fortnight after the operation The ulcer was ligatured *en masse*. Many other cases will soon be reported as a result of the attention which is now being directed to the subject, and possibly not a few failures will be passed over in modest silence.

Now death from gastric hæmorrhage is nearly always death from *recurrent* hæmorrhage. Further, there is no need to operate quickly in order to avert peritonitis as in cases of perforation; and the patient is usually alarmed and depressed to fainting during the bleeding. Lastly, a day or two usually intervene between successive hæmorrhages. These considerations would lead one to defer operation until actually present hæmorrhage had ceased and shock had passed away. But one must not expect reaction after large hæmorrhages to restore to the pulse its original strength and volume. When the patient has fairly rallied and his or her extremities have become warm, with or without external heating appliances, if operation is decided on the sooner it is done the less will be the risk of being overtaken by another (and possibly fatal) bleeding.

The next consideration is the *mode* of operating. It must be remembered that while the gastric ulcers which perforate and cause peritonitis are nearly all on the anterior wall, those which perforate and bleed are, in a large proportion, on the posterior wall and especially such as adhere by their bases to the pancreas or to its near neighbourhood. Therefore, when these latter have been exposed by operation it has generally been found difficult simply to take up the bleeding point and to tie it securely. Resort has been had either to ligature of the ulcer *en masse* or to the actual cautery, and the result has been disastrous[4] I am inclined to think that I was fully justified in my case in preferring to separate the adhesions of the stomach to the pancreas and diaphragm, scrape the ulcer and close the resulting gastric wound by suture. This was, as I have said, a long process, but if a patient is in fairly good condition, is kept warm, is not allowed to bleed, and is not over-dosed with anæsthetic, and if also the vigilance of the antiseptic precautions is not allowed to relax, I do not believe that a moderate prolongation of an operation seriously endangers its success. But I hold it to be of the first consequence, especially with feeble subjects, to produce only so much anæsthesia as is necessary to protect the patient from serious pain. The dose should not be increased as a luxury for the surgeon. I do not recommend separation of a bleeding ulcer from the pancreas or the diaphragm as a routine procedure, because I think shorter and easier measures will generally suffice.

---

[3] Brit. Med. Jour., March 23rd, 1901

In these days the old general rule of surgery to cut down upon a bleeding vessel and to tie it is modified by many exceptions, especially in parts where compression can be [illegible] ssion is seldom if ever [illegible] Even temporary pressure [illegible] upon to permanently check bleeding from the vessels of the stomach. Experience of gastric operations proves that, where practicable, a ligature should be put on before removing the forceps. Not only has it often proved difficult to find the bleeding point or points in operations for gastric hæmorrhage, but also, when found, the source of bleeding has sometimes proved so friable or in such a situation that effective ligature, even *en masse*, has not been possible. And, as I have already said, the cautery has not given good results. There remain, however, at least three other powerful agents which may be used in nearly every part of the body as protective against recurrent hæmorrhage, viz: (1) rest (local and general), (2) aseptic measures, and (3) gauze (especially iodoform gauze) packing. The first two can be used more or less successfully by the physician, but they can be effected more thoroughly and more lastingly by the surgeon, and the third, of course, can only be employed by the surgeon.

It is well known that the arrest of bleeding from an eroded vessel in the stomach is brought about by the formation of a clot in it. It is often assumed when the bleeding recommences that some excitement of the circulation has displaced the clot. From what takes place in regions of the body more open to observation I should infer that usually not mechanical displacement but septic disintegration has been the chief agent in starting the bleeding afresh. What a difference there is in the value of plugging in the present as compared with the past! That difference is mainly due to the fact that formerly a septic wound used to be plugged with septic material, while now an aseptic wound is plugged with aseptic or with antiseptic material. No doubt the secretions of the stomach, especially of the normal stomach, have a bactericidal power, but examinations of matters vomited show that power to be limited. In a case of recent severe hæmatemesis there is a stomach containing blood and perhaps food at the temperature of the body and in contact with a diseased area, the ulcer, and with a mucous membrane not secreting normally.

The stomach can be washed out through the gullet, and some medical men recommend hot-water lavage for cases of hæmatemesis. It is rather a disturbing process of which I have had no experience in cases of hæmorrhage, but I should hesitate to condemn it on mere *a priori* grounds. An objection to it is that if the asepticity of the stomach is to be preserved the lavage must be frequently repeated, and in many patients it can only become a gentle process when the patient has been long accustomed to it There is also a slight risk of perforating a diseased stomach. And what if the diagnosis were wrong and the stomach already perforated!

If a stomach is opened and cleansed by the surgeon, how is the cleansing or asepticising to be made permanent or at least enduring? A very extensive experience by various surgeons agrees that if, by a successful gastro-enterostomy or pyloroplasty, or even mere dilatation of the pylorus, we remove all spasmodic or other obstruction to the free flow of stomach contents into the small intestine, a great and a rapid improvement takes place in the health of the stomach. Indigestion ceases and ulcers heal. In ordinary cases, therefore, one of these operations alone would suffice. Mr. Caird recommends the performance of a gastrostomy as a mode of giving rest to the stomach and regards such a procedure as analogous to one for drainage of a diseased urinary bladder. Mr. M'Gillivray points out an essential difference: urine is always flowing into the latter, but we are not obliged to be always putting food into the stomach. Moreover, Mr. Caird suggests that the gastrostomy should be done by Witzel's method. The calibre of the small rubber drain or catheter generally used in Witzel's gastrostomy compares unfavourably for drainage with the one-and-a-half inch or two-inch diameter of a gastro enterostomy wound.

A question with a practical bearing is *how* do gastro-enterostomy, pyloroplasty, and Loreta's operation come to act so beneficially on peptic ulcers? The explanation generally adopted is that they prevent stasis of the stomach contents due to constriction of the pylorus But duodenal ulcers lie beyond the pylorus altogether, and peptic ulcers are found up to, but not beyond, where bile and pancreatic juice enter the duodenum. It is reasonable to infer that the presence of these juices is a protection against gastric ulcer. We were, most of us, I think, until recently under the impression that much bile in the stomach would cause discomfort and probably vomiting. A remarkable case is reported by Mr. B. G. A. Moynihan[5] After an accident which completely separated the duodenum from the jejunum, that surgeon closed the distal end of the duodenum and did a gastro-jejunostomy. All the secretions of both the liver and pancreas now necessarily only reached the intestine by flowing backwards through the stomach. The patient lived for two months in "perfect health" Death then resulted from perforation caused by the Murphy's button.

I suggest that the curative effect of gastro-enterostomy, &c., is due in some measure to the passage of bile and pancreatic juice into the stomach. My colleague, Mr. L A Bidwell, tells me, as supporting this suggestion, that traces of bile can be found in the stomach contents after gastro-enterostomy.

To return for a moment to Mr. Caird's suggestion already referred to no mere gastrostomy would bring bile into the stomach. Still, it must be admitted that a sufficiently *large* gastrostomy opening would permit frequent and complete lavage of the stomach through it, and the patient could assist this by swallowing copious draughts of hot water—an act which would be very grateful to him and tend to remove one of the sources of distress which patients fed wholly by the rectum have to endure. I, therefore, think that a simple direct gastrostomy wound, large enough to admit the finger, might have been good practice in such a case as that of the patient in Case 2 *suprà;* and that if performed on the day after her admission into hospital it would have saved her life, especially if the pylorus had been well dilated at the same time During the operation a quick search for the bleeding point might have been successful, but a prolonged search would not have been justified considering her state. The proper anæsthetic would have been gas with oxygen. I have tried it for gastrostomy and can strongly recommend it. Mr. R. W. Lloyd was the administrator It has the great advantage of not being followed by vomiting.

If there is anything in the hypothesis that the cure of peptic ulcers by certain operations is due partly to regurgitation of the secretions of the liver and pancreas it would be reasonable to treat gastric ulcers by administering orally preparations of those secretions or perhaps of the fresh glands themselves; and all the more so, because even the hypertrophy and contraction of the pylorus often present with gastric ulcer—e g., in Case 3—are probably of reflex and irritative origin. The ulcer, the hyperacidity, the pyloric contraction opposing the stomach movements, and at least one other as yet unknown cause, probably bacterial, act and react to exaggerate each other. Attack one or two of these successfully and the rest are weakened. Get the ulcers into a healing state and it is likely that the pyloric contraction, unless cicatricial, will abate. This is one of several reasons why I respectfully differ from those who altogether discard Loreta's operation. But "that is another story."

---

[4] Von Mikulicz writes that, besides his successful case, "I have opened the stomach three times for acute hæmorrhage. The ulcer lay in the neighbourhood of the pylorus in the posterior wall and adhered in two of the cases to the substance of the pancreas. The base and surroundings of the ulcer were so much infiltrated that securing the vessel with a ligature or with a suture was out of the question [illegible] with applying the therm[illegible] [illegible] specific. In a publication last year, 1900, von Mikulicz does not modify his opinion or add to the above facts

[5] Brit. Med. Jour., vol ii, 1900, p. 1403, and more fully on May 11th 1901.

It is possible that some readers, bearing in mind that I am only a surgeon, may think that I have formed an exaggerated idea of the seriousness of gastric hæmorrhage from only hearing of very severe cases. In truth, I am brought into contact with many cases of lateral curvature of the spine which have a *history of present or past symptoms of gastric* ulcer and slight hæmatemesis.

There remains for consideration not so much the value as the applicability of iodoform gauze packing. The objection usually urged to it is that a gastrostomy opening would have to be left for its removal. But such an opening as I have endeavoured to show, in partial agreement with Mr. Caird, might not be an unmixed evil. Or a small piece of gauze could be left in the stomach to pass per anum when free. It could be fixed against the bleeding surface by sutures attached to neighbouring points of the stomach wall (mucosa and submucosa). Every case must, of course, be considered on its own merits, and in the present state of our knowledge decision must often be difficult, both to the physician who does justice to surgery and to the surgeon who acknowledges, as he must, that gastric hæmorrhage treated medically does not, as a rule, prove fatal, even if severe, and that such operations as gastro-enterostomy and the excision of gastric ulcer are themselves not free from danger. But the dangers of gastro-enterostomy diminish with increasing experience of the individual operator and with the general advance of gastric surgery. Murphy's button is most likely the best means of performing gastro-enterostomy, especially for the use of the operator who is deficient in general experience. The one objection to it is its tendency to fall back into the stomach or to stick in the opening instead of passing on through the intestine; both these accidents have occurred to me but they were easily dealt with. It is a quick mode of operating, but it should not be applied in a hurry. I suspect that many failures attributed to it have been really due to want of care and deliberation in placing, adjusting, and fixing it and the margin of the two wounds it has to keep in contact, and in some cases, to faulty construction of the button.

A collection of 75 operations done in various ways by Billroth, von Hacker, Czerny, and von Miculicz, made by the last-named showed the following decreasing percentages of mortality. The operations were for non-malignant stricture of the pylorus and for gastric ulcer "without severe complication." To the end of 1886, 62·5 per cent.; 1887 to 1890, 42·1 per cent.; 1891 to 1894, 22 2 per cent.; 1895 to the beginning of 1897, 10 per cent. Von Miculicz gives the following decreasing mortality percentages for the individual operations, the periods compared being before the end of 1890 with 1891–97. Resection, 39 3 per cent., reduced to 27·8 per cent.; gastro enterostomy, 43·5 per cent., reduced to 16 2 per cent.; pyloroplasty, 23 8 per cent., reduced to 13 2 per cent These figures are calculated from a total of 234 cases, collected from various sources. There can be no doubt but that increased personal experience in the selection of cases, in the choice of operation and in the mode of operating and increased practice in gastric surgery are capable of further reducing the death-rate, and, indeed, they seem to have already done so.

With regard to the degree of danger of gastric ulcer in general when treated medically, I think that those physicians who speak of having treated so many hundreds of cases with, say, 95 or 98 per cent. or even 100 per cent. of recoveries are not giving their experience quite correctly. I suspect that inquiry would show that many of these cases had not been under the observation of these physicians for more than a few months, whereas gastric ulcer goes on, or keeps recurring only too frequently, for years. My patient in Case 3 had had gastric symptoms for 25 years, which represent about 150 of what some people seem to call "cases."

I think the statistics advanced to prove Loreta's operation to be no safer than gastro-enterostomy must be fallacious Loreta's operation went out of fashion at a time when all these gastric operations were more dangerous than they are now. It is certainly free from one of the serious complications of gastro-enterostomy—viz., the danger of the so-called "vicious circle," the passage of the stomach contents, not into the efferent loop of intestine, but into the afferent and so backwards through the duodenum into the stomach. The use of Murphy's button seems to protect against this complication of gastro-enterostomy. Why should mere dilatation of the non-cicatrised pylorus be dangerous? True, it involves a gastrotomy unless done by invaginating the stomach wall on the finger. But a mere gastrotomy is a very safe procedure, as is proved by surgical experience in the removal of foreign bodies. But in favour of gastro-enterostomy remains this possibility, that it may be more likely to give a permanent cure of the ulcer itself and of the chronic gastric catarrh. Of course, a pyloroplasty can effect every object attainable by Loreta's operation, but it must be a more serious procedure except in the case of a cicatrised pylorus so rigid that it would be dangerous to stretch, and then a pyloroplasty might not be applicable.

One of the strongest arguments in favour of surgical treatment of gastric cases which have bled severely is that it generally gives permanent health to the stomach.

Grosvenor-street, W.

VITALITY AFTER SEVERE INJURY.

BY W. H. CLAYTON GREENE, B.A. CANTAB., M.R.C.S. ENG., L.R.C.P. LOND.

WITH reference to the power of living after severe injury, in illustration of which a case of rupture of the inferior vena cava with survival for two and a half hours was recorded by Dr. Adrian Caddy in THE LANCET of May 25th, p. 1464, I think the following case of perforation of the stomach, diaphragm, pericardium, and heart with other injuries in which death occurred after nine hours may be of interest

A man, aged 49 years, was admitted to St. Mary's Hospital on April 2nd, at 12 noon, under the care of Mr. H. W. Page, who has kindly given me permission to publish these notes. The patient, while working on a ladder in Wimpole street, fell on to the area railings and impaled his left side. When seen in the casualty department he was conscious but was suffering from severe shock. His pulse could not be felt, but the heart could be heard beating faintly, rapidly, and irregularly. He had evidently lost a great quantity of blood, his clothes being completely soaked by it. His forehead was bathed in perspiration and his extremities were very cold On examining the injured part a large gaping wound was found in the left hypochondriac region from which omentum protruded and the blood flowed; several ribs appeared to be fractured, but no detailed examination was made at first owing to the condition of the patient. Four minims of strychnine were injected at once and the patient was taken to the wards where hot bottles were placed round the body and limbs A pint of saline solution and two ounces of brandy were given by the rectum and, the left median basilic vein having been dissected out, two pints of saline solution were injected into the circulation. The patient's condition improved so much—the pulse being now easily felt, about 118—that at 1 25 P.M. the wound was more thoroughly explored, but nothing definite as to the source of the bleeding could be made out and it was therefore plugged with cyanide gauze. Four minims of strychnine were injected again at 1 30 P.M. Mr. Page, on arrival at 3.15 P.M., saw the patient and decided to attempt the controlling of the hæmorrhage which still continued Since his admission the patient had been conscious and could reply to questions, but he complained of great pain in the cardiac region He was taken to the theatre and was partially anæsthetised and the wound was again explored, but it was found that the injury was so extensive as to render any surgical interference useless Collapse came on rapidly, so three pints of saline solution were injected per rectum and into the subcutaneous tissues Four minims of strychnine were repeated The patient was taken back to the ward where he regained consciousness, but he gradually sank and died at 9 P M

At the post mortem examination the following injuries were revealed There were a large irregular wound in the left hypochondriac region with fracture of the sixth, seventh, eighth, ninth, and tenth ribs, complete perforation of both walls of the stomach from before backwards, perforation and laceration of the diaphragm, extensive collapse of the left lung, and perforation of the pericardium and of the left ventricle of the heart (this latter organ is now in the museum) The pleural cavity on the left side was full of blood and the stomach had been pushed right up through the opening in the diaphragm There was a small amount of blood stained fluid in the peritoneal cavity but very little in the pericardial cavity

I think this case is of interest as illustrating the great vitality of the body after severe injury and also as a proof of the great value of injections of saline solution It, indeed, seems marvellous that a man could survive for nine hours after receiving such injuries as those described above

St Mary's Hospital

THE MORBID ANATOMY AND ORIGIN OF THE VARIOUS PRESYSTOLIC MURMURS HEARD AT THE APEX

By O C GIBBES, M D ABERD, M R C P LOND,
PHYSICIAN AND PATHOLOGIST TO THE HOSPITAL FOR DISEASES OF THE HEART, SOHO-SQUARE, W

THE assumption that the presystolic murmur is pathognomonic of mitral stenosis has steadily lost ground since Flint first drew attention to its occurrence in cases of aortic regurgitation where no stenosis of the mitral orifice was found on post mortem examination Subsequent experience has shown us that there are various other conditions in which we may have a presystolic bruit sufficiently similar to that of mitral stenosis to render correct diagnosis difficult, if not impossible

The morbid conditions that have been found in cases where the presystolic murmur has been heard during life may be briefly classified as *follows* —1 Stenosis of the mitral orifice, with or without any other valvular disease 2. Obstruction of the mitral orifice by a pedunculated thrombus attached to the left auricle[1] 3 The heart dilated and hypertrophied, the mitral orifice dilated, the cusps and chordæ normal, the aortic orifice competent, and the valves normal[2] 4 Dilatation and hypertrophy of both ventricles; the curtains of the mitral orifice thickened and rough at their margins and admitting three fingers; the aortic valves thickened but competent[3] 5 Aortic insufficiency, left ventricle much hypertrophied (*a*) All the aortic segments contracted and insufficient, but the mitral orifice competent and the curtains normal[4] (*b*) Weight of heart 32 ounces, aortic segments all thickened and shrunken The mitral orifice dilated (admitting three fingers easily) and the anterior cusp thickened, but the chordæ not thickened or shortened[5] (*c*) Weight of heart 35 ounces, aortic valves all thickened, but only slightly deformed The mitral orifice much dilated (admitting five fingers), the cusps and chordæ normal[6] (*d*) Heart weighed 19 ounces. The aortic valves incompetent and much deformed, the anterior and right posterior cusps united along their margins so that the regurgitant current must have been directed towards the anterior mitral valve; the mitral orifice dilated (admitting four fingers), the cusps and chordæ thickened but not shrunken[7] (*e*) Weight of heart 32½ ounces The right posterior aortic valve deformed, the regurgitant current being directed towards the septum ventriculorum The mitral orifice normal in size and the cusps healthy[8] 6. Aortic stenosis, heart weighed 27½ ounces; the aortic valves fused together but permitting regurgitation, the current impinging on the anterior mitral flap The mitral orifice dilated (admitting three fingers readily), but the curtains not shrunken or thickened[9] 7 Hypertrophy of the left ventricle in kidney disease The pericardium healthy, aortic valves competent, one slightly thickened; the mitral orifice normal size, the anterior flap slightly thickened, and the chordæ thickened and shrunken[10] 8 Hypertrophy and dilatation of the right ventricle, secondary to atheroma of the pulmonary artery and its branches[11] The pericardium adherent throughout. The heart dileted and hypertrophied The aortic valves normal The mitral orifice dilated The valves healthy or thickened[12]

In addition to the above a pseudo presystolic murmur is sometimes heard at the apex in aortic regurgitation, owing to the heart's action being quickened and the ordinary aortic regurgitant murmur being so prolonged that it almost runs into the first sound This, however, is not the murmur described by Flint, for on listening carefully the interval between the murmur and the first sound can be detected, and it generally becomes quite distinct after the patient has had a rest I have had several of these cases and in one instance I was able to verify my diagnosis Sansom[13] has also recorded one case in which a post mortem examination was made

Phear,[14] in an article published in 1895, collected post-mortem records of 46 cases where a presystolic murmur had been present without there being any actual stenosis of the mitral orifice, but these cannot be taken as any numerical guide to the frequency with which this form of presystolic murmur occurs in actual practice

Guiteras[15] and several subsequent writers have expressed the opinion that it is frequently heard at the apex when mitral stenosis is absent, but I think that this statement requires some qualification, for although it is not a very infrequent occurrence when dilatation and failure occur in [illegible]
an hypertrophied [illegible]
ing the latter half [illegible]
running up to the [illegible]
noted as "presystolic" in our case books, yet the murmur described by Flint is very rare indeed in spite of the frequency of aortic regurgitation

In discussing the character of these murmurs it is as well to take that of mitral stenosis as a standard for comparison, the peculiarities and variations of that murmur being well known Taking first the typical murmur of that disease we may ask, "Is it ever present under other morbid conditions?" The answer to this question is undoubtedly in the affirmative The murmur itself may be just as harsh, and although the first sound may not be as slapping as that of mitral stenosis it may be much sharper than normal, the whole bearing such a striking resemblance that it is impossible to distinguish between them

I have only met with one case of Flint's murmur, and unfortunately I was unable to verify my diagnosis as a post-mortem examination was refused, but the physical signs were unmistakeable and left no doubt concerning the absence of mitral stenosis The chief points of the case were as follows

The patient was a male, aged 36 years He had had rheumatic fever in 1879 and 1890 The first signs of failing compensation appeared in 1888 When I first saw him in November, 1899, compensation had broken down and he complained of anginal pains, dyspepsia, and dyspnœa. The apex beat was very diffuse and could not be located by palpation, but on percussion and auscultation it appeared to be in the sixth left intercostal space, in the mid-clavicular line. Pulsation was marked in the carotids and the pulse was irregular and collapsing. On percussion the right limit of dulness was two centimetres beyond the right border of the sternum in the fourth intercostal space. On auscultation the first and second sounds of the heart were distinct at both base and apex, the second being reduplicated over the whole præcordial region. A loud double aortic murmur was heard over the base of the heart, while below the level formed by the junction of the fifth costal cartilages with the sternum the aortic systolic murmur was lost, the diastolic became shorter, and a presystolic began to be heard, gradually increasing in intensity towards the mitral area. In the sixth left intercostal space, the mid-clavicular line (presumably the apex), the second sound was reduplicated and following the reduplication a short distinct early diastolic murmur could be heard, and after a soundless interval a harsh crescendo presystolic murmur, occupying about a third of the diastole and ending abruptly in a sharp first sound. It was not a "slapping" first sound, but was certainly sharper than normal. I then examined the patient in the recumbent posture and found the aortic diastolic still present at the apex, but the harsh presystolic was absent and a blowing systolic was heard instead; there was no trace whatever of any presystolic murmur and the sharp character of the first sound was gone. I again listened when he was standing up and found that the presystolic murmur had returned. Three days later I again examined him in both positions and found the same physical signs present. I therefore listened at the apex while he was in the act of lying down in order to note the transition from the presystolic murmur to the systolic. I found that after he had lain down there were two or three beats with the presystolic murmur present; then it seemed, as it were, suddenly to fizzle out with a kind of splashing sound (it is very difficult to describe correctly these transition sounds) and the murmur resolved itself as already described, the aortic diastolic being conducted to the apex, where a blowing systolic murmur was heard, there being no trace of any presystolic sound whatever. The case is an interesting one apart from the alteration in the rhythm of the murmurs because I listened knowing that I was dealing with a Flint's murmur and could not detect any practical difference from the ordinary murmur of mitral stenosis. The transition sounds gave me the impression that when the patient was standing something had become invaginated into the mitral orifice obstructing the flow of blood from the auricle to the ventricle, and that on lying down it had been dragged out permitting regurgitation to take place. Taking into consideration the rhythm of the murmurs and the nature of the transition sounds I think that there must have been some reversal of blood-currents, whether due to some other cause than the force of the regurgitant blood-current on the anterior mitral flap can be only a matter of conjecture in the absence of post mortem evidence, but two causes appear to have been in operation. First, a larger expenditure of muscular force was required of the heart in the erect than in the recumbent position and therefore the muscle vibrations would be louder; and secondly, gravity would cause the regurgitant current to impinge on the anterior mitral flap with greater force in the erect than in the recumbent posture.

When compensation fails in mitral stenosis a less typical presystolic murmur may be heard, bearing the character of a low-toned rumble increasing in intensity towards the end of the diastole and terminating in a "slapping" first sound. These physical signs are sometimes closely imitated in young patients with adherent pericardium; the murmur, however, under these circumstances is extremely variable in rhythm and the presystolic may rapidly change into an early or mid-diastolic murmur, the latter being of more frequent occurrence than the presystolic, owing probably to the fact that not only is the heart dilated and hypertrophied, but there is also a varying amount of irregular fibrosis present.

The third form of murmur that is heard in mitral stenosis occurs when the heart's action is much quickened and compensation has failed still further. Under these conditions a short presystolic murmur may be present that is little more than an extension backwards of the first sound. This form may be imitated in any other form of valvular disease when compensation is failing. It is fairly common and completely passes off when compensation returns.

Various explanations have been given of these murmurs, Gairdner's[16] theory being now generally accepted with regard to its occurrence in mitral stenosis (I am assuming that these murmurs are all presystolic in rhythm). His view is that "with very rare exceptions such murmurs depend upon contractions of the auricular ventricular orifices and consequent interruption to the flow of blood out of the auricle during its contraction" and only occur when the blood is being expelled from the auricle. Whether the murmur is due to "vibrations of the stenosed mitral curtains"[17] or to "audible manifestations of the eddy in the blood-stream"[18] does not for the moment concern us, for I cannot agree with the theory that it is solely due to the flow of blood from the auricle to the ventricle. On the contrary, I hold that it is a compound sound and consists of three parts. 1. Audible vibrations of the muscular wall of the right ventricle. Bramwell[19] when writing on reduplication of the second sound tells us that "the right ventricle is by reason of the increased blood-pressure in the right cavities of the heart first stimulated to contract." That exactly expresses my views of what takes place in mitral stenosis, for I believe that in consequence of the high tension produced in the pulmonary blood-vessels by stenosis of the mitral orifice the right ventricle commences to contract before the left and gradually assumes not only the functions but the rhythm of the left auricle. The result of this partial asynchronism is that the muscle vibrations of the right ventricle are heard while the left is in diastole, imparting a crescendo character to the murmur and causing its intimate connexion with the first sound. A further result of this is that the pulmonary valves close before the aortic. 2. The vibrations produced by the flow of blood from the left auricle to the left ventricle and called by Gairdner the "auriculo-systolic murmur." 3. The "slapping" first sound. This forms an integral part of the murmur in consequence of the muscular and valvular portions of the first sound being only partially asynchronous and the former constituting a portion of the murmur.

Several theories have been brought forward with a view to explain the presence of a presystolic murmur in aortic regurgitation. Flint,[20] Guiteras,[21] Bramwell,[22] Maguire,[23] Sansom,[24] Potain,[25] Lees,[26] and Rolleston[27] consider it due to vibrations of the anterior mitral cusp although they differ as to the mode in which these vibrations are produced. Others agree with Gibson[28] who suggests that "the mingling of the two currents in the neighbourhood of the apex of the heart" is probably the cause. Phear[29] considers that it is due to relative or actual shortening of the chordæ tendineæ causing virtual narrowing of the mitral orifice; Fisher,[30] referring more especially to the presystolic murmur of adherent pericardium, suggests that "possibly there is a loss of muscular tone in consequence of deranged nervous mechanism or some unusual alteration in muscular action" and "vibrations of the muscle wall are set up by the inrush of blood on contraction of the auricle." The theory I myself have brought forward with regard to mitral stenosis is equally applicable to all presystolic murmurs.

Comparing the above theories I find that Gibson's and my own are the only two that explain the occurrence of the murmur in the various morbid conditions I have detailed I cannot agree with Gibson's theory because I do not believe that sound can be produced in the blood eddies themselves, for Nicholl's researches show that "it is impossible to produce sound in a moving liquid as long as it is free from air."[31] Furthermore, we know that the murmur is present regardless of the rapidity of the blood-currents, being equally present when the mitral and aortic orifices have been dilated, contracted, and normal. I am more in agreement with Fisher's theory, but it will be seen that while agreeing with his premisses I differ from his deductions.

Taking into consideration the character of the murmur when it occurs in diseases other than mitral stenosis we find that both the typical murmur and its variations are closely imitated. These variations in the presystolic murmur of mitral stenosis are generally considered to be due to changes in the intensity of the vibrations produced by the auriculo-ventricular blood-current, as a result of failure of compensation. But this loss of compensation is almost entirely due to failure of the muscular power of the right ventricle and my contention is that the variations that occur in the murmur are due to feebleness or absence of the muscle tones consequent on such failure, the vibrations caused by the auriculo-systolic blood current playing a minor part. The heart remains compensated as long as it has sufficient muscular power to supply the left ventricle with enough blood to carry on the circulation. As the constriction increases and more muscular force is required, so the murmur becomes louder and more and more prolonged, being augmented during its latter part by an increased intensity in the vibrations caused by the auricular ventricular blood-current. When compensation fails the valvular vibrations are lost and the muscle tones diminish, thereby lessening the intensity of the murmur. Ultimately a low-toned rumble only may be heard ending in what is little more than an extension backwards of the first sound, or should the heart fail still more both the muscle and valvular vibrations may be absent and a long slapping first sound alone remain.

In some cases of aortic regurgitation the presystolic murmur, like that of mitral stenosis, is probably due to the two sets of vibrations above mentioned, but this is not the case with all, for some of the morbid conditions which I have detailed render it impossible that any abnormal vibrations could have been produced at the mitral orifice; in these cases, therefore, the murmurs are due to muscle vibrations alone. In Ewart and Rolleston's case a pedunculated thrombus was attached to the posterior and lower part of the foramen ovale, it "passed through the mitral valve and projected into the ventricle as a purple mass." The right ventricle was "dilated and hypertrophied," the left was "somewhat dilated and its walls a little hypertrophied," and the aortic valves were healthy. The mitral orifice admitted four fingers, the flaps "were perfectly healthy, but as regards the function of closing the orifice their occupation was usurped by the clot, which kept the flaps permanently apart and at the same time in sufficiently close contact with it to interfere with any free vibrations of their membranes." Ewart and Rolleston explain the origin of the murmur as follows: "We may infer that the murmur and the thrill which preceded systole were produced by vibrations in the blood-stream and that the considerable diminution in the area of the orifice was in itself, apart from its shape, and in the absence of any vibrating edge or lip, a sufficient cause for their production." My objection to this theory is that vibrations of blood are not audible; as Clifford Allbutt[32] says: "The blood does not run in the air as water over gravel; the murmur we hear is due to vibrations of surrounding structures—chiefly the walls of the heart, set up by the vortices within them; the heart is the fiddle and the blood is the bow." And even if this murmur was solely due to vibrations of the walls of the heart, initiated in this manner, why do we also get a presystolic murmur when the orifice is dilated, or why, as Fisher[33] points out, are the eddies of blood which must occur among the interstices of the chordeæ tendineæ and columnæ carneæ during the diastole of the normal heart always silent? The murmur may in part have been due to vibrations produced in the walls of the heart by the blood-stream, but in my opinion it was chiefly due to the muscle vibrations of the right ventricle.

The case of hypertrophy of the right ventricle referred to by Fisher is very interesting. I find from his paper[34] (I have been unable to get any further notes on the case) that the woman in question was an out-patient at Guy's Hospital in 1888 under the care of Dr. Wooldridge, having "a well-marked presystolic murmur and a soft systolic murmur," at the apex. After admission the presystolic murmur disappeared, in consequence I presume of the rest, and a soft diastolic murmur was audible between the nipple and the sternum. Four years later the patient was readmitted under the care of Dr. E. C. Perry with "a rough rumbling presystolic and a soft blowing systolic murmur in the mitral area." A presystolic thrill was also present. On post-mortem examination the heart was found to be much enlarged, "weighing 18 ounces, the apex was formed mainly by the right ventricle, which was greatly hypertrophied, the muscle wall measuring three quarters of an inch in diameter; the tricuspid orifice measured five inches and the mitral three inches and three quarters. The aortic valves were healthy, but the pulmonary had a few small vegetations upon them." There was marked atheroma of the pulmonary artery extending into its small branches, the hypertrophy and dilatation of the right ventricle being apparently due to obstruction in that vessel.

In this instance we have to account for a rough rumbling presystolic murmur and a presystolic thrill by the condition of the right ventricle alone, the slight dilatation of the mitral orifice being the only abnormality in the left side of the heart. In many cases of mitral stenosis the responsibility of the circulation rests entirely on the right ventricle; in this case the same thing occurred, but the obstruction was situated further back, being in the pulmonary vessels and not at the mitral orifice; the result, however, was the same and the same murmur was heard, the excessive hypertrophy of the muscle adding to the intensity of the murmur which certainly could not have been produced by the auriculo-systolic blood-current.

Summarising the morbid conditions we find that the presystolic murmur has been proved to be present under the following circumstances 1. Obstruction of the mitral orifice by sclerosis and adhesion of the cusps or by invagination of an auricular thrombus. 2. Dilatation of the mitral orifice with normal cusps and chordæ. 3. The mitral orifice of normal size but roughened margins. 4. Insufficiency of the aortic valves, with (*a*) normal mitral orifice and curtains; (*b*) dilated mitral orifice but normal cusps and chordæ; and (*c*) mitral orifice dilated and cusp and chordæ thickened. We also find that it is equally present when the regurgitant current is directed towards the anterior mitral cusp and when it is directed toward the septum, when the regurgitation is free and when it is limited, and when there is no aortic or mitral regurgitation at all, the only morbid condition common to all being dilatation and hypertrophy of the heart. I therefore think that I am justified in saying that the presystolic murmur cannot entirely arise from the auriculo-systolic blood-current as the supporters of the Gairdner theory claim.

When writing on mitral stenosis[35] I have contended that partial asynchronism of the ventricles caused the muscle tones to be audible during the diastolic period. If the cases are carefully studied where the presystolic murmur has been present in spite of the absence of mitral stenosis it will be seen that the two conditions common to the whole of them are: (1) hypertrophy of the heart muscle and therefore increased muscle tones; and (2) loss of compensation, producing partial asynchronism and thereby causing the muscle tones to be heard during the diastolic period, the intensity of the presystolic murmur varying in proportion to the amount of hypertrophy present.

IMPROVED WORKMEN'S DWELLINGS.—The fifty-seventh report of the Metropolitan Association for Improving the Dwellings of the Industrial Classes states that the rate of mortality in the dwellings of the association is considerably below that for the whole metropolis. The cash statement after payment of the year's expenditure shows a credit balance of £8805.

ENDOWMENT OF A BED AT SUNDERLAND INFIRMARY.—A donation of 1000 guineas was some time since received from Mr. R. A. Bartram, a local shipbuilder, and his wife, to endow in perpetuity a bed for the special treatment of women, and the general committee decided to name a small ward the "Bartram Ward" and to place in it a tablet to commemorate the gift, a formal unveiling of which recently took place. The tablet bears this inscription: "The Bartram Ward commemorates the gift of one thousand guineas, the gift of Mr. and Mrs. R. A. Bartram of Thornhill Park, Sunderland, who thus endow in perpetuity a bed for the special treatment of women.—25th October, 1900."

LONDON HOSPITAL.

TWO CASES OF CÆSAREAN SECTION.

(Under the care of Dr. G. E. HERMAN.)

IN most operations a mere summation of the results obtained gives an erroneous idea as to the exact danger, for in such a case we calculate the mortality from all cases recorded without any attention being paid to the circumstances and conditions under which the operation was performed. In no operation is this more true than for Cæsarean section. In some of the cases the operation is performed only after a protracted labour and after repeated attempts to deliver with forceps and version. In other cases the Cæsarean section is performed before the onset of labour, with the patient under the most favourable conditions. In eight years, from 1886 to 1894, 22 cases were recorded in the London Hospital and of these nine women died and five children; this gives a maternal mortality of 40 per cent. Zweifel of Leipsic[1] had two deaths in 30 cases. That the operation in itself need not cause much risk to the mother is shown by the fact that it has been performed more than once in some patients; in one case Cæsarean section was performed four times.[2]

CASE 1. *Flat rickety pelvis; conjugate two and a half inches; first child delivered by cephalotripsy; second by Cæsarean section, followed by amputation of the body of the uterus.*—The patient's first child was delivered by perforation and cephalotripsy in the London Hospital in August, 1898. Her last menstruation ceased on July 28th, 1899. She had had slight bleeding for two days between two and three months previously, and one day's bleeding a fortnight previously. She was admitted into the London Hospital on May 27th, 1900. She then thought herself about nine months pregnant. The girth at the umbilicus was $35\frac{3}{4}$ inches. The distance from the pubes to the top of the uterus over the convexity was 16 inches. There was marked rickety curving of the femora and tibiæ. The pelvic measurements were as follows: anterior interspinous, 10 inches; intercristal, 11 inches; external conjugate, $6\frac{5}{8}$ inches; diagonal conjugate, $3\frac{1}{4}$ inches; and between the ischial tuberosities, $3\frac{3}{4}$ inches. After her last delivery the obstetrical conjugate was measured by Johnson's method and was found to be $2\frac{1}{2}$ inches.

The patient having been given the alternative of delivery of a dead child by perforation and cephalotripsy, or of a living child by Cæsarean section followed by sterilisation, preferred the latter Dr. Herman therefore performed Cæsarean section on May 29th. The placenta was implanted on the anterior uterine wall and there was therefore considerable hæmorrhage. (Attempts had been made beforehand to detect the placental site but without success.) After extraction of the child and placenta the broad ligaments were first tied and divided internal to the ovaries; then the vesico-uterine peritoneal fold was divided and the peritoneum was pushed down off the anterior surface of the uterus, and then the uterine arteries were tied. The body of the uterus was then cut away at about the level of the internal os by incisions which sloped downwards, so that the stump left was gutter-shaped. The two lips of the stump were then stitched together with catgut, the posterior lip being folded over the anterior. The abdominal wound was then closed. The duration of the operation was 33 minutes. The child, a female, weighed 7 pounds $2\frac{1}{2}$ ounces. The measurements of her head, five hours after birth, were vertico-mental, $5\frac{1}{8}$ inches; occipito-frontal, $4\frac{5}{8}$ inches; sub-occipito-frontal, $4\frac{1}{4}$ inches; bi-parietal, $3\frac{3}{4}$ inches; bi-temporal, $3\frac{1}{2}$ inches; and bi-mastoid, 3 inches. The patient recovered without bad symptoms and mother and child left the hospital well on June 23rd.

CASE 2 *Fibroid growing from the lower segment of the uterus, filling the pelvic cavity, obstructing delivery, and causing severe pain; Cæsarean section, followed by amputation of the body of the uterus; recovery*—The patient, aged 31 years, was admitted into the London Hospital on August 25th, 1900. She was married at the age of 19 years and by her first husband she had five children. Each labour was induced at about the sixth month on account of pain from which she suffered. She was not told anything about a tumour. The medical man who advised the premature termination of pregnancy was dead, and the patient knew not the names of the other medical men called in in consultation, hence it was impossible to get accurate information as to the reasons for inducing labour. She became a widow three and a half years before admission. For two years she had suffered from symptoms of ulcer of the stomach, vomiting, and occasional hæmatemesis; and for these she had been kept in bed for 20 weeks. She was married for the second time in February, 1900, and her last menstruation ceased on March 30th. Her complaints were of pain in the left lower abdomen, the lumbar region, and down the back of the left leg, and of pain in passing urine, which she had had for five months She had been losing flesh for a year On examination there was a swelling rising out of the pelvis and reaching nearly to the umbilicus. At the top of this swelling on the right side was a hard nodule of the size of an egg. The vaginal mucous membrane was of a bluish colour. The fœtal heart could not be heard. By the vagina the cervix uteri was high up. The left posterior quarter of the pelvis was occupied by a hard swelling of the size of an orange, almost immoveable and not separable from the cervix uteri. In view of the uncertainty of the diagnosis it was thought best to explore the tumour. This was done on Sept. 14th. The uterus had the appearance of pregnancy; the nodule on the top was a fibroid, the intrapelvic swelling was also a fibroid, so low down that the fingers could not be got underneath it, and it seemed to be between the folds of the broad ligament. The patient was anxious to have a living child. It was clear that she could be delivered only by Cæsarean section. It was therefore decided to let the pregnancy go on to near term and then to perform Cæsarean section.

The patient recovered from the exploratory incision without bad symptoms and left the hospital on Oct. 6th, but she returned to the hospital on the 31st on account of pain in the lower abdomen and back which she took to be pains of labour. She remained in bed till Nov. 2nd. Her pains were then better and there was no sign of labour, so she was allowed to go home. She returned on the 27th complaining again of pain which was so severe as to keep her awake at night. The fundus uteri was two and a half fingers' breadth below the ensiform cartilage. The greatest girth of the abdomen was $37\frac{3}{4}$ inches. The distance from the symphysis to the top of the uterus, over its convexity, was 15 inches. There was no dilatation of the cervix. The fœtal head was felt in the right iliac fossa. No indication of placental site was made out.

Cæsarean section was performed by Dr. Herman on Dec. 5th. The placenta was implanted on the anterior wall of the uterus, so that the amount of blood lost was more than usual. After extraction of the child and placenta the broad ligaments on each side were transfixed, tied, and divided internal to the ovaries. The uterine artery on the right side was then tied. The uterus was then pulled up to get at the left uterine artery, and it was found that the fibroid which was in the pelvic cavity was not between the folds of the broad ligament, but grew out from the lower part of the uterus just above the cervix. It was nowhere adherent and was easily lifted out of the pelvic cavity. The left uterine artery was then tied, after which the body of the uterus with its fibroids was amputated at the level of the os internum. The stump was treated by sewing the posterior flap over the anterior flap. Owing to the loss of blood from the divided placental site the patient was at this time pale and her pulse was small. As much boiled water as the peritoneal cavity would hold was poured into it and left there. Improvement in the pulse followed almost immediately and by the time the suture of the abdominal wound was complete the pulse was of good volume. The patient presented no bad symptoms, excepting some flatulent pain, until the ninth day, when the temperature rose to 102° F. It then fluctuated between 100° and 101° until the seventeenth day. Examination then revealed a swelling bulging in Douglas's pouch. The patient was anæsthetised and this swelling was cut into from the vagina [illegible]

[2] British and Foreign Medico Chirurgical Review, 1870, vol. ii., p. 270.

birth. It weighed less than five pounds. The tumour was an ordinary fibroid without any sign of degeneration.

Remarks by Dr. Herman.—In The Lancet of May 2nd, 1891 (p. 986), Dec. 16th (p 1508) and 23rd, 1893 (p. 1565), *and July 14th, 1894 (p 77),* I published all the cases of Cæsarean section that I had till then performed in the London Hospital. I now add to them two more performed since, which make the record complete up to the present time. These cases bring the number up to 13. Seven patients recovered and six died. In the six fatal cases the necessity for the operation was revealed by the failure of the natural powers to effect delivery, and the operation was in consequence not performed until the patient had been long in labour. All the cases recovered in which the diagnosis of the conditions affecting delivery had been made during pregnancy, and the operation was in consequence performed before the patient was exhausted by protracted labour. This ought always to be the case; for if the necessity for the operation is ascertained before term is reached it is the simplest of all abdominal operations, for the operator has to deal only with healthy tissues, and the details of the operation are the same in every case. For the notes of Case 1 I am indebted to Dr. A. Gordon Wilson, resident accoucheur, and Mr. W. F. Ellis, clinical clerk; and for those of Case 2 to Mr J. Sherren, resident accoucheur, and Mr. C. Bramhall and Mr. A. M. Simpson, clinical clerks.

BRADFORD ROYAL INFIRMARY.

A CASE OF CARCINOMA OF THE WALLS OF THE STOMACH; PARTIAL GASTRECTOMY; RECOVERY.

(Under the care of Mr. W. H. Horrocks.)

The statistics of partial gastrectomy, including pylorectomy, are on the whole fairly satisfactory. Mr. Mayo Robson in his lectures at the Royal College of Surgeons of England in 1900[1] has collected 572 cases, and of these 398 recovered; this is equal to a mortality of 30 per cent., but if suitable cases are chosen the death rate is much less. For instance, Maydl had only four deaths in his 25 cases, and Kocher had only five deaths in 57 cases. Statistics collected by Haberkant[2] show clearly the higher mortality which occurs when extensive adhesions are present, for under those circumstances the death-rate was 72 per cent., but when there were no adhesions only 27 per cent. of the cases died The improvement of the results in the future will depend chiefly on an earlier calling in of the aid of the surgeon in any case in which the possibility of the existence of malignant disease of the stomach is suspected. For the notes of the case we are indebted to Mr. James Phillips, senior house surgeon.

A man, aged 46 years, was admitted into the Bradford Royal Infirmary in March last complaining of pain after food of six or seven weeks' duration with occasional vomiting and pyrosis at night He had lost one and a half stones in weight in 11 months. He had never been ill in his life before. He was a strong, well-built, healthy-looking man. The tongue was indented and furred. The abdomen was flat In the epigastrium a hard lump was felt, apparently about two inches deep by one and a quarter inches wide, which moved up and down with respiration immediately under the abdominal wall and could be pushed laterally up under the left ribs On distending the stomach with air the tumour was found to be to the right of a resonant area not greater than the normal stomach resonance.

Cancer of the pylorus was diagnosed and on March 22nd an operation was undertaken for its removal. The stomach was pulled out through a five-inch incision and the growth was found to extend from the pylorus five inches along the walls of the stomach. The coronary arteries were ligatured on either side of the growth and the gastro-colic omentum was ligatured off below it. Clamps having been placed on either side of it, the stomach was divided vertically clear of the growth and the open end was closed with two layers of continuous sutures. The first layer passed through all the coats and the two ends were left long and were finally tied together so as to pucker the wound. The growth was cut away and the duodenal end was treated in the same way. Two or three glands were removed from the omentum close to the lesser curvature. An anterior gastro-enterostomy was next done by means of a Murphy's button. The wound was closed with through-and-through silkworm gut sutures. The whole operation took 70 minutes. A gauze drain was left in which was removed on the second day. The patient made an uneventful recovery. The button was passed on the twentieth day and he left the infirmary in apparently good health and with unimpaired appetite on April 20th.

The growth was a scirrhous carcinoma involving the whole circumference of the wall of the stomach for over five inches of its length and stopping just short of the pyloric ring which was normal. The mucous membrane was not ulcerated anywhere and there was no obvious musculature left.

Remarks by Mr. Phillips.—A noteworthy feature in this case was the very slight nature of the symptoms, the abdominal tumour alone indicating the serious nature of the case. The importance of making an abdominal examination in patients who complain of even slight dyspeptic symptoms is emphasised by two other cases of cancer of the stomach which have lately been in the Bradford Royal Infirmary where before the abdomen was examined and the tumour was found secondary deposits had formed and operation was useless. With regard to the operation, the closing in of the stomach and duodenum was found to be facilitated by leaving the ends of the through-and through continuous suture long and then tying them together, so puckering the line of suture and rendering fewer covering Lembert's sutures necessary.

Medical Societies.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Microscopical Demonstration —Exhibition of Patients and Specimens —Cœliotomy.—Perforated Gastric Ulcer.—The Supply of Pure Milk.

A meeting of the above society was held on May 21st, Mr. F. Farrow, the President, being in the chair.

Dr. F. W. Eurich gave a microscopical demonstration illustrating some Tumours of the Kidney.

Mr. J. B. Hall showed: (1) A Stomach on which Gastro-enterostomy had been recently performed; (2) Gall-stones removed from the Common Duct; (3) Sarcoma of the Sheath of the Rectus Abdominis; and (4) Rickets in a Chicken.

Dr. C. F. M. Althorp showed: (1) A case of Excision of the Tongue and Cervical Glands (operation 15 months previously); and (2) a case of Excision of the Breast for Scirrhus (operation two and a half years previously). Both patients were in good health.

Dr. H Angus showed a Spleen from a case of Hodgkin's Disease.

Mr. R. Mercer showed a photograph of a Foot showing great Hypertrophy of One Toe.

Dr. R. H. Crowley showed the following specimens: (1) Cystic Kidney (?) Congenital; (2) Calcareous Pericardium; (3) Thrombosis of the Right Pulmonary Artery and its Branches; and (4) Excessive Dilatation of the Auricles.

Dr. A. Bronner showed the patients in the following cases: (1) Recent cases of Mastoid Disease treated by Transplantation of the Skin; and (2) Extraction of Cataract in a woman, aged 84 years.

Dr. Eurich showed. (1) A Brain illustrating Contrecoup; (2) Intussuscepted Bowel; and (3) Dysenteric Ulcers of the Colon, with Perforation.

Dr. James Kerr showed a boy, aged five years, originally seen for eye symptoms, who about two years ago awoke with the mouth drawn to the left and with paralysis of the right half of the face. This had completely passed off as regards voluntary movements and the boy was now in robust health and could whistle and close the eyes, &c., in a natural manner. But for emotional movements complete paralysis of the right face remained, so that he laughed and cried on one side of the face, and when he was quarrelling with other children the right eye remained widely open and the face on that side was motionless. Such symptoms were commonly associated with lesion of the optic thalamus and they offered several problems as to double routes in the brain.

[1] The Lancet, March 24th, 1900, p. 838.

[2] Archiv für Klinische Chirurgie, 1896, vol. li., p. 484.

Dr. J. B. BERRY read notes on three cases of Cœliotomy. The first was a case of Gangrene of the Omentum. A married woman, aged 43 years, had suffered from abdominal pain and swelling for "some time." She became pregnant and was delivered of a child (her twelfth). After confinement the swelling increased and she was tapped twice, a quantity of foul-smelling fluid being evacuated. Fourteen days after delivery cœliotomy was performed when the subcutaneous fat was noticed to be in a sloughy condition. On opening the peritoneum a mass of gangrenous omentum presented and came away, the pedicle rupturing very readily. It had been lying in a cavity shut off from the rest of the abdominal viscera. This cavity was plugged with iodoform gauze and a boric poultice was applied to the wound. The sloughs in the body-wall gradually separated and the patient made a good recovery. The temperature during her stay in hospital was mostly subnormal and there was diarrhœa from the third to the sixth day. The second case was one of Perforated Gastric Ulcer. The patient was a girl, 17 years of age, who had been seized while at her work with abdominal pain, faintness, and vomiting. There was a history of anæmia and indigestion. The pulse-rate was 98, and the temperature was 100° F. The abdomen was slightly distended, the breathing was thoracic, and the liver dulness was abolished. Cœliotomy was performed 29 hours after the onset of the symptoms. On opening the peritoneum signs of peritonitis were present, but there was no notable extravasation of gastric contents. A small perforation, admitting a large probe, was found on the anterior wall near the lesser curvature which was covered by a patch of lymph. This was inverted and two rows of Lembert's silk sutures were applied. No flushing was employed and no drain was inserted. The patient made a good recovery except for some suppuration in the abdominal wall on the tenth day. In the third case, which was one of Ovarian Cystoma, the patient, a woman, aged 45 years, had complained for a considerable time of abdominal swelling and œdema of the legs. For four or five days she had suffered from fever, the temperature rising to 102° F. in the evening. On opening the peritoneum a large cyst of the ovary was found which contained 17½ pints of turbid brown fluid. The cyst was removed and the patient made a good recovery.

Mr. HALL read a paper on a series of cases of Perforated Gastric Ulcer. He classified gastric perforation into (1) acute or fulminating, and (2) subacute or insidious cases, according to the course of the symptoms. A third class of cases, commonly spoken of as perigastric abscess in which the peritonitis remained localised, should not, he said, be included in the statistics of the more acute cases. The relation of perigastric abscess to the unlocalised form was identical with that of localised appendicular abscess to perforated appendix with general peritonitis. Among the acute or fulminating cases he included all those cases of gastric perforation with the sudden onset of the typical symptoms of acute peritoneal infection. These cases at the present day were operated upon early with most encouraging success. Apart from early operation the condition and quantity of the escaped stomach contents had a considerable influence upon the prognosis. He quoted the figures of Mikulicz as showing the remarkable advance in the result of surgical treatment. Among the insidious or subacute cases Mr. Hall classified those cases in which the typical signs of peritoneal infection were not marked at the onset. He urged that in any case where the possibility of gastric ulcer was present the most careful examination for slight degrees of muscular rigidity and the presence of a tender spot over the stomach should be made. The close inspection of the abdomen was not practised so thoroughly as it should be. No case in which there was the slightest suspicion of perforation should be left unseen for longer than two hours. If at the end of that time it could not be said that perforation did not exist it was far safer to explore than to leave the case undecided. He believed that if this course were adopted the number of lives saved would greatly exceed the number of unnecessary operations. As regards treatment Mr. Hall strongly advocated systematic flushing of the peritoneum, arguing that it was impossible to say in any individual case when the peritoneum was clean and that after flushing any poison that remained was enormously diluted. He also advocated cleansing the peritoneum at the earliest possible moment, leaving the suturing to the last. To combat shock he had the greatest faith in large doses of strychnine given hypodermically. He mentioned a case in which he had given 40 minims of the solution of strychnia in all without producing any symptoms of poisoning.—Dr. W. H. HORROCKS, Dr. T. J. WOOD, and Mr. MERCER discussed the paper, and Mr. HALL replied.

Dr. CROWLEY read a paper on the Supply of Pure Milk He expressed it as his opinion that a great part of the excessive infant mortality was due to defective milk-supply A system working in St. Helen's and Liverpool was described in which the milk was humanised and sterilised, and supplied in bottles, each containing sufficient for one feed and a day's supply being delivered at once. The working of the Manchester Pure Milk Supply Company was also described. Here the milk was not sterilised, but the sources were under the full control of the company, as were all the manipulations, and inducements were offered to the dairymen to prevent any contamination of the milk. The cows were frequently tested with tuberculin. If there was any infectious disease among any of the farm servants the milk from that farm was not used, but the farmer was not put to any loss thereby. The dairies were frequently inspected and precautions of cleanliness were observed by those engaged in milking. The milk was carefully cooled as soon as it was drawn and it was then forwarded to the headquarters of the company without delay. Here it was examined and tested and was put into cooled vats and filtered. It was delivered in sealed bottles or in bulk twice daily. Dr. Crowley thought that a combination of these systems would meet the necessities of the case, and he advocated, if necessary, the municipal distribution of milk.

CAMBRIDGE MEDICAL SOCIETY.—A meeting of this society was held on May 10th.—Dr. L. Humphry related a case of Sudden Death from Meningeal Apoplexy, the patient being a married woman, aged 45 years, who died in the outpatient room at Addenbrooke's Hospital. Death took place in about four minutes, the respiration failing first; there were no convulsions. The necropsy showed a sub arachnoid hæmorrhage affecting chiefly the base and cerebellar space, and the blood was spread in a thin film over the cortex on both sides The cerebral vessels did not appear to be diseased and no miliary aneurysm was found. The left ventricle of the heart was slightly hypertrophied, but the kidney structure was healthy.—Dr. Griffiths described a case of Cylindrical Endothelioma of the Sigmoid Flexure of the Colon The patient was a woman, aged 49 years, who for five months had suffered from obstinate constipation with small stools which were sometimes mixed with blood. On admission to hospital the sigmoid flexure and the descending colon were distended with fæces and an irregular firm lump was to be felt in the pelvis just in front of the left sacro-iliac joint. On opening the abdominal cavity below the umbilicus the lump was found to be a limited endothelioma of the lower end of the sigmoid flexure. This was with some difficulty excised and during the three months which had since elapsed the patient had been comfortable and well.—Dr. Griffiths also described a case of Polypoid Adenoma of the Mucous Membrane of the Small Intestine with Intussusception. The patient, a woman, 17 years of age, was under the care of Dr. Humphry, and for 12 months had suffered from recurrent attacks of pain in the abdomen. During the latter part of the time the onset of pain was accompanied by the appearance of definite swelling in the abdomen which came and went with the pain In the intervals nothing definite could be detected. Latterly there was severe vomiting during the attacks and on more than one occasion blood was found in the motion. The diagnosis being difficult, laparotomy was performed, and the swelling was found to be an intussusception in the small bowel, due to a polypoid adenoma of the mucous membrane A small section of the gut was excised and recovery was uneventful.—Dr Griffiths also described a case of Small celled Sarcoma of the Ileum with Intussusception. The patient was a woman, 19 years of age, who for four months had suffered from pain in the body. This pain came on at times and was associated with much rumbling, but there was neither constipation nor anything abnormal in the fæces. In the right iliac fossa there was a swelling of the shape and nearly of the size of the kidney which could be freely moved about. On opening the abdomen it was found to be an intussusception near the ileo cæcal valve due to a firm polypus one and a quarter inches in diameter. This arose from the mucous membrane and was composed of small cells In addition there was a secondary lump in the mesentery near by, and the lumen of the gut was much narrowed. A portion of the gut and mesentery including the growths was removed, and the patient, who has made a good recovery up to the present time (four months in all), remains apparently free from recurrence —Dr. Lloyd Jones read notes on a case of Appendicitis—a second attack—occurring in a man, aged 23 years. Perforation took place about the eighth day of the illness. General peritonitis ensued, and after some days a localised collection of pus was ascertained to have formed under the diaphragm, on the left side, and the left pleura was found to contain serous fluid. Dr. Griffiths evacuated the pus after resection of a portion of a rib. More than a week later the left pleura was found to contain pus A portion of another rib was resected and the pleura drained The man made a good recovery.

MANCHESTER THERAPEUTICAL SOCIETY.—At a meeting of this society held on May 22nd, Dr. Dreschfeld, the President, being in the chair, Dr R T. Williamson read a paper on the Treatment of Diabetes Mellitus. The importance of varying the treatment (dietetic and medical) according to the form of the disease was pointed out For practical purposes three forms might be recognised: (1) the mildest, in which a rigid diet caused the sugar excretion to cease; (2) the more severe, in which the sugar excretion was not checked by a rigid diet; and (3) the most severe form in which the urine gave a dark brownish red colouration with perchloride of iron. The dietetic treatment suitable for the three forms was described and the importance of discontinuing a very rigid diet in the third form was referred to In the medical treatment of the milder forms of the disease Dr Williamson had obtained better results from salicylate preparations than from other drugs, and he showed charts demonstrating the value of salicylates and the value of aspirin in markedly reducing the sugar excretion quite apart from any restriction of diet. In the most severe forms of the disease with a marked perchloride of iron reaction he had obtained some temporary benefit from large doses of bicarbonate of soda (as recommended by Naunyn), and at the earliest stage of diabetic coma he occasionally had seen slight temporary improvement result from the use of very large quantities of the same drug.—Dr. J. J. Cox had also found salicylate of soda very useful in mild cases of diabetes —The President referred to the importance of looking for a primary disease of which the glycosuria might be a complication. He had thus met with it in two cases of biliary colic and in one of malaria and had found the sugar to disappear with the relief of the primary disease. He also spoke of a neurogenic form, one due to worry and anxiety of business and cured by rest In the severer forms of the disease abstention from milk and bread was advisable so long as the weight of the patient kept up. He had found good to result from the use of salol and salicylate of bismuth, and also occasionally from antipyrin in doses of from 20 to 25 grains twice daily.

WINDSOR AND DISTRICT MEDICAL SOCIETY.—The annual dinner of this society was held at the White Hart Hotel, Windsor, on May 29th Mr. W. B Holderness, the President, being in the chair.—Amongst the guests the Mayor of Windsor, who had kindly granted the use of the Guildhall for the society's meetings, was present. There was a large attendance of members —After the usual loyal toasts Dr Fletcher Beach, in proposing the toast of "The Society,' briefly reviewed the work of the past session and pointed to the increase in the number of members, the good attendance at the monthly meetings, and the satisfactory state of the finances as evidence that the society was supplying a want long felt in the neighbourhood.—Mr. Arnold Thomson having replied, Mr. Noble Smith proposed "The Guests," coupling the toast with the name of Dr. G. Leslie Eastes who, by reading a most interesting paper and by the exhibition of drawings, specimens, &c, had so largely contributed to the successful programme of the session —The toasts of "The Officers of the Society" and "The President" having been received with acclamation the proceedings terminated with the National Anthem.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—The following office-bearers have been elected for the session 1901–2:—Honorary President: Dr. W. J. Smyly, Dublin. President: Dr. Robert Jardine Vice-Presidents: Dr. Samuel Sloan and Dr. J M. Munro Kerr. Treasurer: Dr. John Lindsay. Secretary: Dr. A. W. Russell. Reporting Secretary: Dr. G. Balfour Marshall. Pathologist: Dr. John H. Teacher Members of Council: Dr. J. Coulson Howie, Dr. P. McBryde, Dr. J. C. Herbertson, Dr. D. Macgilvray, Dr. Carstairs C. Douglas, and Dr. Jane B. Henderson.

Reviews and Notices of Books.

Mikrophotographischer Atlas zum Studium der Pathologischen Mycologie des Menschen. (Micro-photographic Atlas for the Study of Human Pathological Mycology.) Von Dr. EUGEN FRAENKEL, Prosektor des Neuen Allgemeinen Krankenhauses in Hamburg. Parts IV. (1900, pp. 27) and V. (1901) Hamburg· Lucas Grafe und Sillem. Price, Part IV. 6 marks, and Part V. 5 marks.

PART IV. of Fraenkel's Pathological Atlas is devoted to the consideration of the Bacillus of Influenza and the Bacillus of Diphtheria It contains 20 photographs on 10 plates. The influenza bacillus was first identified and grown as a pure culture in the winter 1891–92 by R. Pfeiffer in the Berlin Institute for Infectious Diseases, and both his researches and those of Fraenkel have been made on those labouring under the catarrhal form of influenza. They have had no experience of the gastric and nervous forms. The influenza bacillus as grown upon hæmoglobin solutions is extremely small, not exceeding 1 2 μ in length, with rounded extremity, and about one-third of this in breadth. Two rods are frequently arranged end to-end and in old cultures they exhibit a tendency to form threads. They colour with warm dilute Ziehl's solution or with polychromic methyl blue The bacilli are found in cases of influenza upon the mucous membrane from the nose to the lungs. They appear to be capable of exciting serious affections in the central parts of the nervous system and to be the cause of local abscesses and inflammatory processes in the lungs. Separation of the epithelium occurs in streaks in the bronchia and leucocytes escape into the lumen of these tubes. The capillary vessels are congested and the peribronchial tissue charged with leucocytes. Pfeiffer has also shown that in cases of influenza-pneumonia suppurative inflammation of the pleura may occur which is attributable to the influenza bacillus Fraenkel has satisfied himself that the influenza bacillus is the cause of suppurative meningitis. He gives several photographs of the appearances presented. These are somewhat better than photographs of such minute objects usually are and convey a fair impression of the appearances presented even to those who are not experts. In regard to the true specific bacillus of diphtheria, generally named the Klebs-Löffler bacillus, it presents itself as a somewhat plump septated rod which sometimes at one end, sometimes at both, is swollen and clublike. They are very abundant in the false membranes, but are by no means exclusively limited to them, being distributed throughout the tissue of the neighbouring submaxillary lymphatic glands in the tonsils, uvula, trachea, and bronchi, and even in more remotely situated organs such as the kidneys and spleen, though they do not appear to produce in these organs any specific lesions. Death of the superficial epithelial layers, which is the first effect of the settlement of the diphtheria bacillus, is always preparatory to the formation of the false membranes. The bacilli may then penetrate the adjoining mucous membrane. The appearances presented by these bacilli are also shown in a series of photographs. Other parts of the same work deal with Tuberculosis, Lepra, Plague, Typhus, and Cholera.

Part V. completes the first volume of the Atlas, and is occupied with Bacillus Typhi Abdominalis and Vibrio Choleræ Asiaticæ. It is illustrated by eight plates. The parts previously published were devoted to Tuberculosis, Lepra, Plague, Influenza and Diphtheria, Typhus and Cholera. The photographs are well executed—perhaps as well executed with the means and instruments at present at the disposal of the pathologist as is possible, though the definition still falls far short of perfection. In a few pages of letterpress the methods of preparation adopted are described, and each plate is accompanied by an explanation of the appearances presented. The plates are actual photographs and not mere reproductions.

Les Rayons de Rontgen et le Diagnostic des Affections Thoraciques non Tuberculeuses. (*Roentgen Rays and the Diagnosis of Non-tuberculous Thoracic Affections.*) By Dr. A. BÉCLÈRE. Paris: J. B. Baillière et Fils. 1901. Pp 96. Price 1 franc 50 cents.

FOR this small volume, which forms one of the well-known series of "Les Actualités Médicales," we have little but praise. The author has confined himself strictly to the diagnosis of thoracic disease other than tubercle, as the diagnosis of the latter by the x rays has been treated by him in a separate volume. In the introductory chapter Dr. Béclère discusses the various methods employed in making an examination of the chest with the rays and divides them into radioscopy, radiography, simple and stereoscopic, and finally kinematoradiography, to which method the name of Dr. Guilleminot will always be attached. The author then proceeds to give a description of his stand with iris diaphragm for making chest examinations. The shadows seen in the skiagram of a normal chest are well described, the illustration of which (Fig. 1) is excellent. The shadows of the anterior and posterior mediastina are next considered with the lateral oblique method of examination. The shadows cast by the normal and diseased heart are fully discussed, and diagrammatic figures of the shadows caused by distension of the pericardium with fluid are given, which doubtless will be useful in the investigation of cases of pericarditis with effusion.

The next chapter is devoted to the pathological shadows of the aorta and œsophagus, the former of course receiving the larger share of attention. Fig. 5 is a beautiful illustration of an aneurysm of the transverse arch of the aorta. The author maintains, and we think rightly, that hitherto too much stress has been laid on pressure signs in the diagnosis of aortic aneurysm. Radiography demonstrates conclusively that pressure-signs may be well marked in a small aneurysm, while, on the other hand, the radiographic shadow may show the aneurysm to be a large one with hardly any pressure-signs at all. We have seen this in two or three instances. According to Dr. Béclère pressure-signs so-called depend more on inflammatory irritation of the surrounding parts than on the size of the aneurysmal sac. The examination of the œsophagus by the rays with previously introduced metallic bougies is touched upon. The next subject considered in this chapter is that of enlarged bronchial glands and an illustration (Fig. 6) is given of this condition. There certainly is some broadening of the shadow of the base of the heart, but we should hardly have thought it sufficient to justify a diagnosis of enlarged bronchial glands. The shadow appeared to us to be too sharply defined for such a condition. Dr. Béclère takes next the various displacements of the mediastina, anterior and posterior, temporary and permanent, and gives a very good illustration (Fig. 7) of the displacement of the mediastinum in a case of fibroid disease of the right lung, showing the heart completely dragged over to the right side.

The next chapter contains an excellent description of the application of the x rays in diseases of the lungs other than tubercle. The author points out that the pulmonary image is quite clear in a healthy chest from apex to base, with the exception of some ill-defined shadowy lines seen to the right and left to the lower part of the median cardiac shadow. He considers that these shadows are caused by the larger divisions of the bronchi. They are, we think, too low in position for the bronchi and have been shown by other observers on radiographic combined with post-mortem evidence, to be caused by the meeting of the pericardium with the pleuræ. The chapter is brought to a close with a very good description of the use of the rays in the diagnosis of pulmonary emphysema, fibrosis of the lungs, pneumonia, and gangrene.

In Chapter V. Dr. Béclère discusses the diagnosis of diseases of the pleura, and we agree with him that a dry pleuritis shows nothing definite either with the screen or plate. It is far different, however, as the author shows, in pleurisy with effusion, be that effusion serum or pus. In Fig. 10 a beautiful illustration is given of a left empyema in a child. It shows the dense shadow obliterating the ribs which is so characteristic of pus in the pleural cavity. It shows also the displacement of the heart to the right. We are sorry that the author does not give an illustration of a serous effusion for comparison and differential diagnosis. It is also a pity that he does not give an illustration of pneumothorax, as throughout all the range of chest radiography there is no more characteristic skiagram than that of this condition, the clearness of the diseased side with collapsed lung shadow and downward displacement of diaphragm standing out in striking contrast with the healthy side, appearances which should certainly be illustrated in a work on chest radiography. In the final chapter the author considers the diaphragmatic shadow and its movements with respiration and then he proceeds to the modifications observed in thoracic disease. A fairly full bibliographical index completes the work. The volume is printed on good paper which doubtless in a great measure accounts for the excellence of the skiagrams. We can cordially recommend this small book to all physicians interested in this new method of physical diagnosis in diseases of the chest.

The Natives of South Africa: their Economic and Social Condition. Edited by the South African Races Committee. London: John Murray. 1901. Pp 374 Price 12*s.* net.

READERS of that delightful book, "Sketches in Persia," by Sir John Malcolm, will remember the story of a master of a vessel whose failure to use his eyes and dislike of composition led him to comply with an Admiralty Order to the effect that officers of men-of-war when visiting a little-known port should describe the manners and customs of the inhabitants by saying of the inhabitants of Muscat: "As to manners, they have none; and their customs are very beastly." This we fear is too often the attitude adopted even in the present day and any endeavour to increase our knowledge of the manners and customs of the natives of foreign countries ought to be appreciated by every member of an empire which has shown itself to be the greatest colonising power in the history of the world. Information about the natives of South Africa should prove especially useful at the present time and we welcome the issue of the book under notice which is edited by the South African Native Races Committee, a committee which was formed at the end of the year 1899 with the object of collecting accurate information with regard to the social and economic condition of the native populations of South Africa.

The first part of the book deals with the population of the native races and this is followed by an account of the laws and customs and a sketch of native life Under the heading of Annexation and Administration the control of native territory is dealt with and the labour question is fully treated The law of master and servant, savings-banks, labour agencies, education, taxation, the franchise, and the sale and supply of intoxicating liquor are some of the other matters which receive attention From the book it is seen that the native and coloured population are very unequally distributed over the country and the committee state that while in some districts the limits of accommodation have probably been reached, in others, and especially in Rhodesia, the resources of the country have hardly yet been tested They also think that the danger of over population in South Africa as a whole may have been exaggerated, but the increase of the Bantu races is a fact beyond dispute As time goes on it is probable that native races will more and more predominate The chief occupation of the natives is agriculture, and many of those who seek temporary employment at the mines and elsewhere do so with the ultimate object of returning to the land and taking unto themselves wives Among other conclusions come to by the committee is the fact that the organisation of the tribe is breaking up and that the authority of chiefs is waning, though they still hold great power in many districts With regard to the treatment of natives we hope that the time is coming when such a passage as that which we quote below will not be true, but we feel that there are many who still pride themselves upon their contempt for the Kafir or "nigger," as he is more frequently called "While there is little systematic oppression of the natives there is a great deal of what may be called casual cruelty. Farmers, employers, and managers, who 'kick about' and cuff Kafir servants, or who deprive them of their wages, in whole or in part, by tricks or deceit, are apt to go unpunished Prosecutions for such offences are rare Probably, too, the redress for failure to pay the wages of blacks is not so prompt and efficient as is desirable" The book is worthy of serious study and its value is enhanced by maps and tables and a good index

JOURNALS AND MAGAZINES

THE *Monthly Review* for June contains a leading article entitled "The Pyramid of Studies," which is well worth the consideration of all who are engaged in education "Our curriculum," says the writer in his closing words, "is good enough, our manipulation of it makes it futile and barren." General education is being considered, but every word in the article has application to the education of the medical man For this, we all know, ought to be as general as possible up to a certain point, and when differentiated it ought still to bear the stamp upon it of its broad origin Our examiners might well bear this in mind, for they must know it as well as the rest of us, and yet they are largely responsible for the fact that the hero of a hundred successful ordeals is often an ignorant man. "In the teaching of physical science," says the writer in the *Monthly Review*, "we ought not to be bullied by specialists into pretending to believe that those are the best pupils who 'know' most specific sciences or can perform the greatest number of prescribed 'experiments' without being able to make a single step for themselves and without a glimmering of the general logical significance of what they are doing" We speak after perusal of many examination papers set to all classes of medical students, and in our opinion the tests to which the candidates are submitted are too often of just this conventional and narrowing character which in theory we all reprobate In the medical curriculum this is the more wrong because the subjects lend themselves in a way that the humanities do not, to subdivision Many things have to be known exactly and promptly, have, in fact, to form for ever a part of the working equipment of the medical man, therefore it is right that a premium should be put upon the accurate storing and rapid reproduction of facts But the significance of these facts, the inter connexion of them with each other, the relation that one ancillary science bears to another,—these are just as important if medical education is to be anything but a means to the narrow and comparatively insignificant end of a qualification We shall have to change our national methods of education and examination considerably before any value is attached to breadth of knowledge, but the examiners who devise the tests for, and therefore dictate the system in, medical education would do well to see if they cannot make an unconventional start

New Inventions.

A SELF RETAINING PESSARY

NOTWITHSTANDING the modern improvements in the treatment of retroversion of the uterus it still falls to the lot of the practitioner to have to treat such cases in many instances by the prolonged use of the pessary after due reposition of that organ Having met with such a case in which various forms of pessary had been tried only to find that they failed to keep the organ in position or came down as soon as the patient began to walk about, I was led to devise the instrument of which an illustration appears herewith and which has been satisfactorily made for me by Messrs Arnold and Sons under the name of the Special Double pad Pessary It is simply an ordinary glycerine-pad Hodge pessary with the addition of a lower pad which on insertion into the vagina diverges from the lower bar of the pessary so as to lie over the "perineal body" I have found this form extremely useful in large roomy vaginæ which have failed to retain the ordinary appliance It is easily inserted by compressing the lower pad against the bar and can be removed with equal ease by a similar manœuvre carried out within the vagina None of the patients who have worn it have experienced the least discomfort from the presence of the additional pad

THE OPEN-AIR SANATORIUM CHART.

THIS is a combined temperature and weight chart which I think will be found valuable in open air sanatoria One of its features is the utilisation of the fifths of a degree in the temperature scale to serve as "lbs" (units) in the weight scale By the variations in their weight being kept constantly in view the patients in these institutions may be encouraged to persevere in methods of hyper alimentation At the foot of the chart spaces are ruled for daily records of the state of the sputum and the urine, and for making notes of cough, night sweats, hæmoptysis, and action of the bowels The chart has been designed by me and is published by Messrs Reynolds and Branson of Leeds

PREVENTION OF CRUELTY TO CHILDREN —The annual report of the Cornwall branches of the National Society for the Prevention of Cruelty to Children has just been issued and shows that 104 fresh complaints affecting the welfare of 233 children were investigated during 1900 The financial statement was satisfactory The report refers to the good effect that is being produced by medical men in certain localities not readily granting death certificates for infants and young children

THE LANCET.

LONDON: SATURDAY, JUNE 8, 1901.

Metropolitan Hospital Sunday Fund.

SUNDAY, June 16th, is the day selected this year for the simultaneous appeal from London pulpits on behalf of the medical charities of the metropolis. For eight-and-twenty years this annual appeal has gone forth, and the largest and wealthiest community in the world has been invited to spare a few thoughts for the needs of the sick poor and to bestow some contribution in money towards the support of those institutions whose glory it is that they are "maintained by voluntary contributions." The Metropolitan Hospital Sunday Fund has during its existence done incalculable good to the great charities for the assistance of which it was founded, and particularly in one direction to which reference cannot too often be made. In bestowal of the sums entrusted to them for distribution the members of the Committee have always been guided by the strictest impartiality, and by performing their philanthropic duty with justice and discretion have compelled institutions whose administrative manners were at fault to conform to proper business methods. The habits of order thus imported into the management of the resources of all medical charities aiming to be benefited by the Metropolitan Hospital Fund have resulted in a great saving of money for the good of the sick poor. The Prince of Wales's Hospital Fund for London, founded by the KING to commemorate his illustrious mother's diamond jubilee, paid the older institution the compliment of adopting the same attitude towards the hospitals of the metropolis and their allied institutions, and as a consequence the man who gives his money to either Fund feels that he is contributing to charities concerning whose administration he has an excellent guarantee.

The share taken by THE LANCET in the foundation of the Metropolitan Hospital Sunday Fund, and in particular the devoted and practical sympathy which, while he lived, our then Editor, the late Dr. JAMES WAKLEY, evinced in its behalf, would sufficiently explain the deep interest in the Fund which year by year we take; but apart from these personal grounds we endeavour each year to stimulate the public of the metropolis to a sense of gratitude towards their hospitals because we are convinced that in the whole world no nobler work is done than within their walls. Their splendid achievements are ill-paid; their shortcomings are made the subject of strictures from would-be leaders of public thought who seem never to remember the mass of good they might say of the hospitals and never to forget an opportunity of saying ill; and their officials are left time after time to bear as best they can the burden of financial insolvency. But the work goes on, and we plead to the public that it may continue to go on and, favoured by practical support, may succour the sick poor with increasing effectiveness. The conscience of London has not yet been thoroughly aroused upon the question of hospital relief. The great city grows greater, the wealthy city grows wealthier, and the claims on medical charity grow more urgent. How are these claims being met? The answer must be that they are met in a completely unsatisfactory manner. All the large hospitals in the metropolis, save perhaps two, must beg, and beg hard, for their bread; the efficiency of several is crippled by their being compelled to curtail their ministrations. There are hardly any, large or small, that are not living from hand to mouth in a condition of painful embarrassment. That is how the claims of medical charities are being met in London. Yet it is something to belong to the metropolis of the world, and it might be thought that the Londoner (from Highbury to Camberwell, from Chiswick to Bow) would be glad of any opportunity to prove a sense of pride in his citizenship. Once, at least, in every year he has afforded him an admirable opportunity of showing that he is worthy of being on the roll of this vast community; for once a year he can join with his fellow-citizens in an effort to remove the reproach from among them that the harbours of refuge for their sick poor are starving from lack of support Surely, if London desires to prove to the world that immense as she is she is not so shapeless and unwieldy as to be irresponsive to a common movement, Hospital Sunday is the day when she should let a simultaneous impulse stir her. It is fitting that the cause of the hospitals should be interwoven with religion, for the sum and substance of all religion is to help the poor and needy—to love one's neighbour as oneself. But whether a man profess his religion openly under one of its many forms, or whether he prefer to follow the dictates of his own conscience, to one and all the lesson of Hospital Sunday must be the same. It is the lesson of self sacrifice which is as ancient as humanity itself and is its crowning glory.

With such a theme we might be tempted to pass beyond our proper limits and to trespass upon the territory of those whose office it is to kindle consciences. This we do not desire to do, feeling sure that more powerful advocacy than any that could fall from our pen will be brought to aid the cause of the Fund in all the pulpits of the metropolis. But in addressing the public directly rather than our usual circle of professional readers, we do not think we have diverged in any degree from the object of a medical journal. In the supplement which it has been our custom for many years to issue on this day we address a wider audience than is our wont and do our best to arouse our fellow-citizens to a sense of the claims that their less prosperous fellow-men have on their thought and sympathy. The medical profession is daily—nay, hourly—engaged in the devoted service of man. Those only who are of it can speak of the amount of its devotion to this cause, and of the blessing that follows its labours in every by-way of misery in this huge, swarming, wicked city. As medical journalists, then, we feel that we have a right to demand that a share of the burden should be borne by the public, and no better opportunity of practical help could possibly be afforded than the collection for the Metropolitan Hospital Sunday Fund.

The Civil Surgeons at the War.

ON Wednesday last, as will be seen on reference to another column of THE LANCET, a representative body of the civil surgeons who have been employed with the forces in South Africa, and who have returned home, dined together at the Hotel Cecil under the presidency of Sir WILLIAM MAC CORMAC. The occasion was a particularly interesting one, inasmuch as the aid of civilian medical men in time of war has never before, we believe, been sought by the War Office. Civilian medical men have been able to find employment in connexion with ambulance work on previous occasions, and have improved those occasions to the great benefit of the suffering sick, but the services thus rendered to the army have been those of individual volunteers. In the South African war the War Office, embarrassed by the unexpected strength of the foe, unprepared in many directions, and in particular unprovided with a medical staff that was anything approaching the proper numerical strength, appealed to the civilian medical practitioners to come to the help of the country. How that appeal was answered we all know. From desire to be useful, from thirst of experience, from lust of adventure, and, with each and all of these, from love of country, applications poured in for medical appointments in connexion either with the Royal Army Medical Corps or with one of the numerous private hospitals. A system of rigorous selection, in the opinion of the rejected candidates not always discreetly applied, had to be put in force, and there is no doubt that had the country required three times the medical assistance that was asked for it would have been forthcoming.

How well those who were chosen comported themselves has been admitted on all hands. Amid the bitter disappointments and heart-wrenching suspenses of the first few months of our military operations in Natal and Cape Colony there were always two bright spots—the splendid bravery of our troops and the excellent manner in which the medical service of the war was carried out. Never were greater courage and more self-sacrificing devotion to duty under trying circumstances in the battle field displayed than by the medical men, both civil and military, who accompanied our South African army; in the earlier days of the campaign it can also be truthfully said that never was there a finer exhibition of administrative resource and professional skill than in the care of the sick and wounded in the hospitals at the theatre of war. In those terrible days, when all our hearts were wrung with the bloody repulses of our troops in their attempts to relieve the beleaguered cities, the nation had the satisfaction of knowing that all which technical skill and personal exposure to danger could do was being done to afford prompt aid to the soldier on the battle-field. In rescuing the wounded man from the enemy's fire and in relegating him to a place of safety where his wounds could be dressed and his sufferings alleviated, everything that professional foresight could suggest or skilful and humane treatment could provide was forthcoming for the man who was suffering for his country. In the earlier days of the South African war this was the satisfactory position of the service rendered by the medical men, civil and military, to the sick and wounded of our army. We may be sure that the treatment that the wounded received will never be forgotten by them; but after events, when the war was going well, so over-shadowed the successful medical administration that marked the earlier and more unlucky phases of our contest with the Boers, that many people can be found to believe and to state that the whole of our military medical administration in South Africa from beginning to end was a chaotic and criminal muddle. This is an unfair view and one that is not held by thoughtful people. The report of the Royal Commission on the South African Hospitals has shown where the fallacy lies. The Commissioners, speaking of the campaign as a whole, stated that the medical arrangements could not be said to have broken down, in spite of the fierce indictments against them. They found that there was no general or widespread neglect of the sick and wounded and that the conduct and capacity of the medical officers deserved great praise.

This praise the civil medical officers share with the Royal Army Medical Corps. Each body suffered in public opinion partly because they were undermanned and partly because the conditions of warfare were such that medical care could not prevent terrible sickness. But they were not responsible for the undermanning or for the fact that at one time in the campaign a vast section of our army out-marched its supplies. It cannot be laid to their door that Johannesburg is a long way from Cape Town. These facts have now become apparent to all thoughtful members of the public who appreciate the good work that was done by the medical men during the campaign. The Government may not understand where those whose opinion is worth having consider the blame to rest, but everyone else knows. And we can assure the civil surgeons who accompanied our South African field force that their professional brethren are proud of them.

The General Medical Council.

THE seventy-first session of the General Council of Medical Education and Registration was opened on Tuesday, June 4th, in the Hall of the Council, when a commendable desire to get to work was manifested by the disciplinary body of the medical profession. So marked was the rapidity with which the Council disposed of the subjects which came up for the first day's discussion that the PRESIDENT, a sound judge in such matters, was moved to say at the end of the sitting that the Council had got through more business than he had ever previously seen disposed of in so short a time as an hour and three-quarters. We trust that the Council will keep untarnished this fair fame, for the Council board is not the place for unnecessary declamation, and certainly not the place for recrimination, while the members are supposed to hold their places for the good of the profession as a whole, and not that they may "keep up the end" of their particular corporations in any dispute.

Before now we have seen much time spent in the saying of things that would have been better left unsaid. Idle debate has cost the Council much money and will do so again unless every member resolves only to say what will be of practical assistance to his colleagues. But over and above economy there is a very distinct reason why at this session of the Council the members should show themselves at one with regard to great questions and able to differ over smaller ones with cordiality. It seems to us possible that the General Medical Council may find itself compelled to come into collision with the Privy Council, and we need hardly say that in that case it is essential that the members should themselves be solid in the course which they propose to take. An Order of His Majesty in Council has been received by the General Medical Council, the gist of which is that "the kingdom of Italy affords to the registered medical practitioners of the United Kingdom such privileges of practising in Italy as to His Majesty seem just," and that Italy shall accordingly be deemed a country to which the second part of the Medical Act of 1886 applies. Under this Order Italian medical practitioners can, on complying with certain conditions, be placed upon the Medical Register of this country and can practise among us without restriction or limit, and the Order appears to have been made under the idea that English medical men have been offered a similar position in Italy under a new Act. But no such Act exists. It would seem, therefore, that the Privy Council have made, or at any rate propose to make, a bad bargain for the medical profession of this country. The Order, when carried out, may relieve certain British medical men in Italy from anxiety—and we shall be glad if this turns out so; but it may also place upon our Medical Register foreign members of our profession who will find it difficult to appreciate the professional attitude and standard of this country; while the General Medical Council will be compelled to undertake a dangerous responsibility in enrolling them.

The whole question of international reciprocity in medical practice bristles with difficulties. That true medicine is one science wherever practised is a noble fact; and that an honest man is inspired with honest sentiments whatever his race is another; but in a work-a-day world we should have more to go upon than such postulates if we are to devise practical measures of medical reciprocity between foreign countries. The General Medical Council can advise the Privy Council and its opinion ought to be respected. Here is where the General Medical Council must be strong, united, and business-like. The Privy Council is avowedly careless of medical matters. The Vice-President has said in the House of Commons that neither the President nor he has leisure to read the reports of the General Medical Council. The Order in Council has now been made—prematurely we think, but still with the knowledge of the General Medical Council—admitting Italian medical men to our Medical Register. With the General Medical Council is left the discretion to decide how far particular individuals possess a sufficient guarantee of suitability for admission to the roll. It must take care that this discretion is not interfered with or over-ridden by the Privy Council who should also be urged to obtain for British medical men real reciprocity in Italy. A firm stand on the part of the General Medical Council will be much appreciated.

Annotations.

"Ne quid nimis."

ARSENIC IN BEER.

THE third report of the Expert Committee appointed by the Manchester Brewers' Central Association has been issued. It will be remembered that in their first report, dated Dec. 1st, 1900, this committee pointed out that the materials then in use in brewing in Manchester were free from arsenic with the exception of certain sugars. They recommended, therefore, that all beer brewed with these sugars should be recalled and if found to be arsenicated should be destroyed. These measures were effectively carried out, and owing to a commendably prompt action on the part of the brewers the beer brewed in Manchester subsequently was soon proved to be free from reproach. In the second report of the committee, which was issued on Dec. 15th, 1900, the committee actually established that the arsenic found in deleterious quantities in the beer was solely due to the contamination by arsenic of certain manufactured sugars, the arsenic being introduced by the use of impure sulphuric acid. The committee then recommended that a systematic and adequate testing of beer should be at once set on foot in order that the public might be protected from all further mischief. This was to a large extent done, and with good effect. The question of the occurrence of arsenic in other brewing materials had been brought to the notice of the committee and in their second report they promised to examine more fully into this aspect of the matter. The third report just issued is practically the fulfilment of this promise. We congratulate the members of the committee on the efficient manner in which they have conducted their task, so far as it relates to the contamination of beer with arsenic and to the safeguarding of the beer-drinking public. So far, indeed, as the brewing interest is concerned the committee have done all that is necessary. We know how the beer became poisonous and we know how such contamination can be prevented, and we congratulate the committee on the able manner in which they have grappled with the immediate problem placed before them. Yet necessarily they have left many points still in obscurity which are of the utmost importance in public health. Since the beer-poisoning epidemic occurred we have been confronted with the possibility of countless channels through which arsenic may gain access to food or drink. We are face to face also with a point of extreme pathological moment, that in spite of the comparatively small quantities of arsenic found in beers yet these small quantities produced a disturbance out of all proportion to the amount of the mineral irritant present. What, then, is the exact nature of the arsenical compound present in beer?—is it an organic compound? And again, what is the effect, if any, of the process of fermentation on arsenic?—does it possibly elaborate a hitherto unknown compound of arsenic more toxic than arsenic itself? We learn absolutely nothing on these points from the report. Again, the validity of various tests for arsenic must also be made the subject of more prolonged inquiry than this committee were apparently able to devote to it. They pin their faith to the Reinsch test as a qualitative test, while for approximate determinations they recommend the Marsh test, depending upon the production of metallic mirrors of varying degrees of density. As a standard of comparison they recommend a solution of arsenious oxide in water which may or may not represent the same thing as arsenic in beer. They do not attempt to lay down the limits of delicacy of the Reinsch or Marsh test and there is much contention amongst chemists on these points The committee merely remark that in all cases when the *presence* of arsenic is ascertained by this test it is then desirable to estimate the amount by means of the Marsh test which "although not giving an accurate quantitative determination will when properly applied give an approximate estimation of the amount of arsenic present." It is certain that in skilled hands the various tests for arsenic are of extreme delicacy, and since it has been shown that varying infinitesimal amounts of arsenic occur in so many substances it becomes important to have some limitation set upon the amount below which arsenic may be considered to be no longer a poisonous factor. But these are all scientific points inviting considerable scientific research and study which the committee evidently regarded as outside the scope of the inquiry which they were instructed to undertake for the Manchester Brewers' Central Association. One important outcome of the inquiry, however, has been the extremely interesting discovery that if arsenic be present in worts yeast will take up a very considerable portion of it, so that if on examination of the yeast it proves to be free from arsenic the wort may be passed as uncontaminated The committee have examined a great number of brewing materials—something like 663 samples in all. In regard to the source of the contamination of barley before it had been subjected to any manufacturing process they conclude that barley is liable to take up very minute quantities of arsenic when grown upon land manured with arsenicated fertilisers. While this is conceivable we do not find in the report much evidence in favour of this view It appears that a sample of urine obtained from a ewe which had died with many others after feeding off roots grown on land manured with superphosphates was found to contain a small amount of arsenic, "but the quantity operated upon was of necessity very small and no quantitative estimation was possible." Arsenic might have been found in greater quantity in the wool, in which case its origin would most probably have been an arsenical dip.. We ventured to express regret in these columns that the Royal Commission on Arsenical Poisoning could not see their way to deal with the beer question first in order that instant steps might be taken for the protection of the public What a Royal Commission could hardly do in the time at their disposal the Manchester Brewers' Central Association, aided by their committee of experts, have succeeded in doing. They warned the public, they traced the mischief, they destroyed the evil stuff, and they have now recommended to brewers the steps to take to ensure in future the brewing of a beer free from arsenic or at least so free that the minutest analysis will fail to detect it For this they deserve the best thanks of the community. But the Royal Commission on Arsenical Poisoning have an enormous field left open for inquiry and it is a body so excellently composed that we may safely leave in the hands of the members for elucidation the great number of vitally important questions which have arisen out of the beer poisoning epidemic In the public interest this elucidation must be complete and conclusive.

HOMŒOPATHY AND THYROID HYPERTROPHY.

MR. WALTER EDMUNDS in his Erasmus Wilson Lectures[1] draws attention to many important points in the pathology and diseases of the thyroid gland. In regard to treatment he makes one suggestion to which the attention of those who practise homœopathy may be particularly drawn. Mr. Edmunds says: "With respect to cases of operative goitre without symptoms—that is to say, cases in which the presence of the goitre is the only trouble—it seems now to be clearly established that the administration of thyroid gland is the best treatment." This statement at first sight would seem to support the homœopathic doctrine that "like cures like," but the lecturer's further remarks tend to show that this method of treatment offers an excellent example of the futility of the homœopathic creed: "The effects of this treatment are so good that it [thyroid gland administration] must be regarded as a specific remedy; if it is, the enlargement of the thyroid gland must, in part at least, be attributed to an attempt at compensation and that attempt must be unsuccessful, for otherwise the increase in size would not proceed to the large dimensions that it does" Far, then, from being an instance of "like curing like" the administration of thyroid gland in cases of goitre is an example of modern therapeutics in which the products of a secreting gland being in abeyance the deficiency is supplied by obtaining such products from other sources and giving them to the patient, so providing substances which are necessary to the well-being of the organism. This method of procedure is adopted, then, with that idea and not with the object of "curing" the morbid condition of the gland.

THE EXTERMINATING COLLECTOR.

THERE is no better way of cultivating habits of observation and assuredly no pleasanter form of active education than the study of botany in the field. Botany may easily be made the driest of sciences and the morphology of plants the most complex, tedious, and heartbreaking form of knowledge to acquire The surest way to avoid turning the study of plant life into a mere classification of dry specimens is to observe in the open the natural life of the vegetable kingdom. A few hours spent in such a way under the guidance of one who knows the secrets and can point them out is worth more even than the professorial lectures of the Royal Institution. To see and to note the kind of soil in which particular kinds of growths flourish, which kind need shade or sun or wind or rain more than their fellows, which plants grow near which trees, and what is the time of year to find particular stages in the development of them all—these objects make field botany a live and delightful study. They can be achieved, too, and the most valuable lessons learned, without any "collecting." It is not necessary to take home and to dry and to dissect the rare plants for a proper understanding of them. See them in their scarce homes if you are lucky enough to, but, having seen them, leave them there for others to learn from too. In the big museums there are specimens for more detailed study and there are pictures and accounts in the text books. It is only the selfishness, the deficient altruism of the genus collector, that leads to the plucking of rare species in a country like England where these are so often already well-nigh extinct. It is in just the same way that rare birds and rare butterflies gradually get killed out of our country. A letter in the *Times* of June 3rd deals with this subject in discussing the programme of the Essex Technical Instruction Committee for Field Studies, and we are entirely in accord with the views of the writer, Professor Miall. Whether concerned in the teaching of botany or not we are all, as he says, interested in the preservation of our native plants We hope that Professor Miall's letter will have an influence in enlightening the mode of instruction apparently used by certain Essex botanists, even though it prevents the aggrandisement of a few private herbaria; and we are specially glad to see that in a letter to the *Times* of June 5th Professor Raphael Meldola as a co-opted member of the Essex Technical Instruction Committee, not only thanks Professor Miall for his letter, but says that the programme referred to was unofficial and had not been submitted to the committee. When education is the avowed object it must surely be a short-sighted policy which encourages individuals to possess themselves of rare specimens, removing to their private cases objects which might have instructed hundreds of future botanists in the field.

---

[1] THE LANCET, May 11th (p. 1317), 18th (p. 1331), and 25th (p. 1449), 1901.

"THE GOVERNMENT AND THE MEDICAL PROFESSION."

A GENTLEMAN has made a communication to us with regard to the leading article in THE LANCET of June 1st, p. 1551, on "The Government and the Medical Profession," who signs himself "An Onlooker" but who does not do us the compliment of trusting his name to us. The gist of his communication is that Mr. M'Kenna's method of bringing forward Dr. Irvine's case from Mr. Markham's side constituted a pantomime and that the House of Commons, being weary and hungry, objected to hear the matter debated at the dinner-hour. He says that the House preferred fair play and dinner to all else, but what sort of fair play was meted out by Mr. Chamberlain and Sir John Gorst to the General Medical Council, the disciplinary body of the medical profession, we are unable to say. Our anonymous correspondent is very vigorous in his assertions that Mr. M'Kenna's action was directed against Mr. Chamberlain and not inspired by a love of justice. Mr. M'Kenna probably knows the truth of the matter which is really of no consequence whatever. He properly raised a very important question in the House of Commons and whether he did so from a *bon motif* or not is a secondary matter.

THE CEREBRAL PATHOLOGY OF HEREDITARY CHOREA.

AN interesting contribution which throws light on the hitherto obscure pathology of hereditary or Huntington's chorea has been published in the *Revue Neurologique* of May 15th by Lannois, Paviot, and Mouisset. In a previous publication,[1] Keraval and Raviart stated that they found the following changes in the nervous system in a fatal case of hereditary chorea: rarefaction of the perinuclear protoplasm, even to the extent of disintegration, in the large pyramidal and small nerve-cells of the cerebral cortex; an infiltration of small round cells into the pericellular and perivascular spaces; swollen nuclei and faint staining of the protoplasm of the cell-bodies in the nerve-cells of the central convolutions; and similar changes in the cells of the spinal cord, especially in Clarke's column. Weigert's method also showed a diminution of the nerve-fibres in the superficial layer of the cerebral cortex (Exner's plexus) and a moniliform degeneration of nerve-fibres in various depths of the cortex. The "small round cells" alluded to above stained green with Rosin's methods, like the nuclei of neuroglia cells. Kattwinkel who investigated a case found a similar proliferation of small round cells, but regarded them as mononuclear leucocytes. The present case was as follows. A man, aged 68 years, by occupation a gardener, had suffered from chorea since 1872, but since 1896 as the result of an accident the symptoms had grown very severe. His father had died at the age of 80 years from the same complaint, and the patient's only brother, aged 65 years, was a sufferer from chronic chorea for many years. There was no history of alcohol or syphilis in the patient. He was thin and emaciated and had twitching of the face, lips, and eyes resembling grimaces. They occurred during both speech and silence and were accompanied by jerky movements of the eyeballs and of the nostrils. There were also present oscillations of the head and purposeless and choreic movements of the arms, legs, and trunk. On the patient lying down these movements diminished and voluntary effort arrested them for a while. All these movements were incoördinate and arrhythmic. Speech was hesitating and jerky and difficult to understand owing to the irregular movements of the lips and tongue. The general strength was good. No trophic disturbances or troubles of the sphincters were present. There were no stigmata of degeneration, except as regards the ears which showed a marked folding of the helix. The patient was loquacious and was inclined to slight incoherence of speech. There was some arterio-sclerosis. Obstinate constipation prevailed. The urine was free from albumin or sugar. The patient died from cachexia in March, 1900. The necropsy showed that all the internal organs were small and wasted in appearance. There was old tuberculosis of both apices of the lungs. The brain was of normal volume. Examination of the ascending frontal convolution after staining with Nissl's method showed an infiltration of small round cells in the molecular layer, but the medium-sized and small blood-vessels appeared normal. The nuclei of these round cells were blue and homogeneous in appearance, and were clothed with a pellicle of protoplasm unlike normal neuroglia cells. These cells occurred in nests of two, three, or four, and in the pericellular sacs of the larger nerve-cells they were numerous and conspicuous. The pyramidal cells showed an excess of yellow pigment in proportion with the age of the patient. Some pyramidal cells were pale and almost uniformly stainless. Only the larger cortical vessels showed proliferation of the perivascular sheath, especially in their course through the white matter. The ascending parietal convolution showed similar changes. No degenerated nerve fibres could be found with Marchi's method in Exner's plexus. The cervical spinal cord showed with Nissl's method a normal condition of the nerve cells. The spinal nerve-roots and meninges were normal. Hence the lesion was one of the cerebral cortex and from its nature it appeared to be incurable.

THE JUBILEE DINNER OF THE ISLINGTON MEDICAL SOCIETY.

THE dinner in commemoration of the fiftieth year of the above society was held in the Victoria Hall of the Criterion Restaurant on June 5th. Dr. James Grey Glover was in the chair, and among the guests were Sir William Turner, K.C.B., Dr. W. Bruce of Dingwall, Dr. Mitchell Bruce, Inspector-General Grant, Sir Albert Rollit, M.P., Sir John Glover, J.P., Mr. T. Lough, M.P., and Dr. Barlow, the newly appointed Dean of Peterborough, until recently vicar of Islington. After the usual loyal and patriotic toasts Dr. Glover proposed the toast of "The Islington Medical Society." He gave a sketch of the foundation of the society in 1850, there being 12 original members, of whom only one, Mr. Jackson, survived. He, although 87 years of age, would have been there that night but that he was suffering from his ninth attack of influenza. The speeches were interspersed with songs and musical sketches contributed by Dr. W. K. Byrne, Mr. Thomas Jago, Mr. Seymour Dicker, and others. The toast of "The Guests" was proposed by Dr. Alexander Morison and replied to by Sir William Turner and others. Great praise is due to the secretary, Mr. David Keele, for the success with which everything passed off, and the society may congratulate itself upon a very fitting jubilee festival.

NAILS IN BUNS AND CHEESE.

A CORRESPONDENT informs us that within a month he has heard of three tacks being found in buns and a bent nail three-quarters of an inch long in a piece of cheese. One of the tacks was not discovered until it had entered the mouth of the person eating the bun and the presence of the nail was also detected in the same way. In the case of an adult who properly masticates his food the chance of swallowing a foreign substance of this kind is perhaps a remote one, but in the case of children who have not their full complement of teeth or are careless, as children usually are, the presence of tacks in buns is a very serious matter and grave harm might result if the tacks were swallowed. The nail probably fell into the cheese during manufacture and the tacks were no doubt accidentally dropped into the dough together with the currants, having previously got amongst the fruit when the box containing it was opened. Such accidents in the preparation of food are always, of course, possible, but with due care they can be minimised. We feel sure that the attention of those who are responsible for the preparation and manufacture of articles of food likely to be "adulterated" in this way need only be drawn to the serious consequences that may arise from want of care to insure a remedy in the matter.

PLAGUE IN CAPE COLONY.

A TELEGRAM received at the Colonial Office on May 30th, gives the following statistics of plague for the week ending May 25th:—Fresh cases: Europeans 4, coloured persons 8, Malays 3, Indian 1, Chinese 0, natives 5, total 21. Corpses found: Europeans 1, coloured persons 4, Malay 1, Indian 0, Chinese 0, natives 0, total 6. Deaths, including corpses found: Europeans 3, coloured persons 8, Malay 1, Indian 0, Chinese 0, natives 4, total 16. The total cases to May 25th were Europeans 169, coloured persons 301, Malays 48, Indians 9, Chinese 1, natives 138, total 656. The total deaths were Europeans 55, coloured persons 155, Malays 35, Indians 6, Chinese 0, natives 57, total 308. One case occurred among persons under naval and military control. Infection in the town of Port Elizabeth has become more widespread and cases have occurred among persons living in the centre of the town.

DENTISTRY AND THE SERVICES.

FROM time to time the complaint is made that many recruits are lost to the services because adequate attention is not given to the men's teeth, and quite recently the question has again arisen in connexion with the medical examination of volunteers for the war in South Africa. The British Dental Association has taken action on the subject, but we understand that the Government have for some time past been making experiments in the matter which is not such a simple one as on the surface it seems to be. The military authorities, too, in the belief that it might be possible to save recruits to the service if dentists were employed at recruiting stations, have both at London and at Manchester had the teeth of recruits thoroughly examined, but the experiments proved a failure, for the results were practically *nil*. It has also been suggested that many men who are invalided out of the service might be saved to it if their teeth were properly attended to, as dyspepsia consequent on dental defectiveness is a frequent cause of men being invalided out of the service, and the military authorities have taken steps to carry out this recommendation, which, we believe, emanated from the generals commanding at Aldershot and at London and from the principal medical officers at those stations. Recently the War Office have been asked to send out to the army in South Africa four dentists with a view to prevent the invaliding of men by reason of "bad teeth." The British Dental Association were applied to for advice as to instruments, furniture, &c., and have recommended four dentists who will start almost immediately, if they have not already done so, for South Africa. The question of prevention of invaliding by a proper supervision of teeth is one which deserves and is likely to receive much attention, but as an aid to recruiting the matter is, we are afraid, doomed to failure for many reasons. In the first place we may mention that "bad teeth" is often inserted in recruiting registers when it is only one item against men who are constitutionally unsound and the entry would be more true if syphilis, scrofula, &c., were inserted in the place of "bad teeth." Possibly the authorities might amend their entries, but to argue that because a large number of recruits are rejected on account of "bad teeth" all these men might be saved to the army if their teeth were looked at by a dentist is absurd. But granting that a fairly large number of these might be gained to the army there is a practical difficulty in the working out of the scheme which may not have occurred to those who urge its advantages. Would the men requiring dental aid be attended to before being "attested"—i.e., passed *legally* into the army by making the declaration before a magistrate, which is necessary to place them under the "Army Act"? If so, there is nothing to prevent them from changing their minds after receiving the benefits of skilled attention and declining to enlist. On the other hand, if the men are actually accepted as soldiers in the legal sense alluded to, leaving the dentistry to be carried out subsequently, what is to become of them meanwhile? Take the large recruiting centres where men are enlisted for all regiments and corps. The men who are *passed* are sent off the same day to the depôts or regiments they are intended to join. If the teeth cannot be "rectified" that day the men must be housed in some quarters or barracks on the spot; or else they must still be sent off to their destination with an intimation to the commanding officer that they must not be considered really "sound" until the dentist has done with them. A dentist would therefore be necessary at every small station. In either case considerable expense would ensue which would only be justifiable if it could be shown that the number of men gained was large enough; and as the evidence tends to prove the contrary the authorities would be unwise to act precipitately in the matter. With regard to the Royal Navy there is less need for any alteration in the existing condition of things. Every medical officer in the Royal Navy is now specially trained in dentistry at Haslar and passes a practical examination in the subject before he leaves the hospital. Moreover, a complete set of dental instruments is supplied to each ship as part of the new outfit of surgical instruments and two surgeons are specially employed at Portsmouth and Plymouth to attend to the dental requirements of the men at these important ports.

DEATH UNDER CHLOROFORM.

ON May 29th a man, aged 42 years, a stevedore, died under chloroform at the Seamen's Hospital, Royal Albert Docks. The patient was suffering from hydrocele for which he desired to be treated as it had occasioned him considerable pain for some time. The assistant resident medical officer administered chloroform on a towel, but after a few inhalations the patient became very restless and struggled violently. When almost under the anæsthetic, and while the parts were exposed previously to preliminary cleansing of the skin, the patient suddenly ceased to breath, the face became deeply congested, the pupils dilated and the pulse began to fail. Artificial respiration was instantly commenced and was maintained. After a minute or two the breathing seemed about to be re-established, the pupils contracted, and the pulse revived a little. The improvement, however, was only evanescent. Hypodermic injections of ether and strychnine proved useless. Oxygen was inhaled during artificial respiration and the battery was freely applied. As there was no response Mr. J. Cantlie, at Dr. J. Catto's request, cut down upon the heart, opened the pericardium, and applied digital compression to the ventricles.

There was, however, but little, if any, contraction induced, and it was only when one pole of the battery was applied to the anterior inter-ventricul groove that the cardiac muscle contracted, and then only for a few times. An interesting fact noted during the application of the battery was, that when a certain area in the inner aspect of the left chest was accidentally touched by one of the poles of the battery, pronounced contraction of the muscles of the left chest and of the left shoulder and arm ensued. This, after happening once or twice, was more fully investigated, with the following result. With one pole of the battery over the course of the left pneumogastric in the neck, on a level with the upper border of the thyroid cartilage, and with the other pole touching a spot in the inner aspect of the fourth and fifth intercostal spaces in a line drawn vertically downwards from the nipple, contraction of the muscles of the left shoulder and arm took place. Production of this phenomenon was limited to an area of about the size of a crown-piece. The contraction consisted of a pronounced spasm of the muscles of the left pectoral region of the left shoulder: the whole shoulder and left arm seemed to be hitched upwards violently. The heart seemed also to be raised in harmony with the left shoulder, but this appearance may have been deceptive. When the pole of the battery was applied on the surface of the skin over the "excitable area" noted within the chest a similar but much milder contraction resulted. This phenomenon is given in detail as not only an interesting physiological fact, but also as a possible explanation of the local and left-arm pain experienced in certain cardiac lesions, the "excitable area" being for the most part on that part of the chest wall immediately superficial to the apex of the heart. The post-mortem examination was made and reported upon by Mr. Angus Kennedy. The evidence given at the inquest showed the viscera, including the heart, to be quite healthy and the jury returned a verdict "That deceased died from syncope due to the administration of chloroform."

THE CULTIVATION OF DISTANT VISION.

THAT the vision of many children for distance is below the average and that it is capable of improvement by exercise are the topics dwelt upon by Mr. Brudenell Carter in an address lately delivered before the Society of Arts. He pointed the moral of his story by referring to the events of the present war in which the advantages of clear, acute, and rapid vision for distant objects have been very distinctly demonstrated. Some years ago Mr. Carter satisfied himself as the result of the examination of the sight of a large number of children in London elementary schools, and subsequently of children born and bred in the country, that town children cannot see distant objects as well as country children do and he attributes this difference to the circumstance that the town child never looks at anything smaller than the people around him or other objects seen under a large visual angle, whilst his range of accommodation is ordinarily limited to the length of a short street or the opposite side of the way. The country child, on the contrary, has constantly before him an expanse of landscape with various objects seen under small visual angles. Assuming Mr. Carter's statement to be correct the question is whether the distant vision of a town child can be improved by systematic training. It is obvious that several things have to be considered in matters of this kind, as the acuteness of sensibility of the seeing organ, the varying conditions under which it is exercised, and the mental alertness in receiving impressions as well as judgment in drawing correct conclusions from the impressions transmitted to the brain. As Mr. Carter observes, the statements so frequently made in the daily papers that the average vision of Boers is superior to that of English soldiery is only superficially true. The Englishman accustomed to town life makes no allowance for the purity and transparency of the air of South Africa and therefore misjudges distances; accustomed to the unceasing activity that surrounds him in a town, his attention is not attracted, as his eye wanders over the wide and quiet areas of the veldt, by a slight motion, a difference in colour, or a peculiarity in form that is instantly observed by the watchful Boer. Mr Carter justly says that an unaccustomed person would probably see the small image of a horse, man, or beast just as well as the Boer, but he would be both less accurate in his perception and less prompt in his interpretation of it. It is, then, not so much the eye as the brain that requires education; the southron who becomes a Highland gamekeeper soon rivals the north-country man in the quickness with which he discovers his quarry, and whilst it does not seem probable that any amount of practice will effect much diminution in the size of the smallest object that a particular eye can see, great improvement may be obtained by exercise in other directions, and we endorse Mr. Carter's recommendations that the vision of all children should not only be carefully tested but that they should be regularly trained to distinguish differences in the form and colour and movement of external objects, as well, perhaps, as for lateral vision. Our eyes are wonderful results of evolution, but they are by no means perfect instruments, and there is no reason why they should not, with the parts of the brain with which they are connected, undergo further development both in the extent and precision of their functional activity.

A DRAMATIC "ADMINISTRATION."

SUPPORTERS of the modern theatre are wont to boast that, whether the methods of to-day do or do not tend to the production of great literary plays, at any rate there is enormous improvement upon former times in the manner in which plays are put upon the stage. Thus we have Shakespeare's plays, they maintain, so represented that an audience may see his characters in just such actual surroundings as those in which the dramatist conceived of them as moving. We behold the very colours of Italy and the streets of her towns, and Juliet makes love out of a real balcony. In this way history is made vivid and education may be advanced. In spite, however, of a general striving after realism and a close imitation on the stage of the "real thing," there are certain traditional and entirely false representations that seem to have a permanent hold on the English stage. One of these is the stage "doctor." The striking characteristics of this gentleman are a supernatural and most depressing solemnity and an inconceivable rapidity in the construction of prescriptions, which seem to flow from his finger-tips almost before he has sat down to write them He is also accustomed to appear in a frock-coat and black tie, whether his presence is demanded in the heart of the country on a warm summer's day or in London at an hour when he would naturally be in evening clothes. Inaccuracies of this kind are, however, only amusing and probably help the picture dramatically. Moreover, always to dress a particular kind of man in a particular way on the stage serves to mark him out plainly for the audience, much as "This is a wall," written upon the primitive hoardings of the bygone stage, adequately represented structures usually composed in reality of brick and stone. When, though, an inaccuracy or an anachronism is too blatant it distracts attention from more important features of the performance, and the critic resents it all the more when the rest of a production is well in keeping with the times and places represented. For these reasons we wish that Sidney Carton had recourse to some other method than that of inhalation when he wishes to render Darnay powerless and to take his place in prison The Reign of Terror, which is the time represented in *The Only Way*, was in 1793, and the idea of anæsthetisation by the inhalation of drugs was mooted for the first time in 1800 by Sir Humphry Davy This, of course is most likely not a familiar fact to the average theatre-goer, but most people know that chloroform was not introduced till many years later and many of them must be a little puzzled by its use in Mr Martin Harvey's prison scene The anachronism is really to be put upon the shoulders of Charles Dickens, for in this scene the play follows the "Tale of Two Cities" very accurately Since, however, the adapter has a pretty free hand elsewhere in departing from the details of the book he might well have taken the opportunity here to improve upon the author in a matter of historical accuracy Mr Harvey may certainly be congratulated upon his "administration" which is begun without the "patient's" knowledge, and though of short duration appears to have a remarkably lasting effect

THE DIAGNOSIS BETWEEN EXTRA-UTERINE PREGNANCY AND ABORTION

THE danger of mistaking extra uterine pregnancy for abortion is not sufficiently appreciated In the *Journal of the American Medical Association* of May 11th Dr H N Vineberg has published a useful paper in which the symptoms of the two conditions are carefully compared He refers to several cases in which women had been under treatment for weeks and had been curetted for a supposed uterine abortion when the condition present was tubal pregnancy He condemns the plan of attempting to curette the uterus without complete anæsthesia The operation can then be performed only imperfectly Moreover it should be preceded by a thorough examination under anæsthesia so as to exclude the possibility of ectopic gestation The following cases illustrate the difficulty of diagnosis A woman gave a history which pointed to simple abortion at the third week of pregnancy Examination which was not quite satisfactory owing to a thick abdominal wall and flatulent distension of the intestines, seemed to confirm this diagnosis, only a slightly enlarged uterus and a patulous os were discovered She was admitted to hospital to be curetted Under anæsthesia Dr Vineberg was surprised to find behind the uterus an ill defined mass which seemed to be an inflammatory exudation After curetting the uterus and removing considerable decidual tissue he determined to ascertain the character of the mass by vaginal incision It proved to be made up of old and recent clot As the ruptured tube was not accessible it was removed by abdominal incision Recovery was uninterrupted Sometimes the patient leads the practitioner astray by a misleading history Thus a woman after a period of amenorrhœa of 17 days began to lose blood A week later she had abdominal pain with persistence of the flow She made light of her symptoms and ignored the advice to be curetted While at business she expelled a mass one day which she asserted was the fœtus She triumphantly said, "I told you it would come away of its own accord, several others have formerly" Three weeks later she was suddenly seized with symptoms of collapse while at stool, and with difficulty was taken home in a cab When seen six hours later she was extremely anæmic, and had a weak pulse of 120 She was apathetic and did not seem to suffer pain The abdomen was large, fat, and hard. On vaginal examination an irregular mass was felt behind and to the left of the uterus Ruptured tubal pregnancy was diagnosed and consent to the performance of an operation was obtained on the following morning But when the patient was placed on the table she became collapsed The abdomen was rapidly opened; it was full of clots, among which a 10 weeks fœtus was found. She did not rally and died an hour later The flow attending a ruptured tubal pregnancy is usually less profuse and more irregular than that which accompanies abortion The former is more likely to occur as a mere "show" which comes and goes, the latter is more continuous But there are numerous exceptions Dr Vineberg has seen very profuse uterine hæmorrhage in tubal pregnancy. Martin reports a case in which it was so severe as to be fatal On the other hand, miscarriage may threaten for a time with a very scanty flow, which may even be irregular, coming and going as in ectopic pregnancy But when a woman has passed her period for a few days only and begins to have an irregular and scanty flow suspicion of ectopic pregnancy should be entertained On the other hand, rupture may take place in ectopic pregnancy without the missing of a period In one case Dr Vineberg observed rupture 17 days after an apparently normal period Some writers have laid stress on the "colicky" nature of the pain in extra uterine pregnancy But the fact that the pathological lesions vary is, apart from other considerations, sufficient to account for differences in the pain in different cases In one case the sac ruptures, in another it is expelled through the ostium abdominale (tubal abortion), in a third there is hæmorrhage into the tubal wall As a matter of fact the character of the pain is very variable It may be sharp and lancinating or "bearing down" as in dysmenorrhœa, it may resemble labour pains or ordinary colic, it may be characterised by a tearing, agonising sensation which cannot be endured, or it may be of a throbbing nature like that attending an inflamed ovary Again, pain of any kind may not be a prominent symptom and its existence may be elicited only by repeated questioning The expulsion of a decidual cast or of membrane is regarded as a sign of great value But no membrane may be discharged in a great number of cases, the decidua being cast off in shreds or undergoing degeneration, or membrane may be cast off unnoticed in the blood clots Moreover, the patient may say that she has passed membrane, which was really only organised clot Lastly, the microscopist cannot distinguish between the decidual cells of a uterine and a tubal pregnancy As to physical examination, in a fat and rigid abdomen it is very easy to overlook a slightly enlarged tube Dr Vineberg rightly insists on the necessity of regarding with suspicion every case of apparently early abortion and of making a complete examination under an anæsthetic in every case which does not run a simple course

THE ARMY MEDICAL SERVICE

WE have already announced that Surgeon General J Jameson, C B, honorary surgeon to the King, Director-General of the Army Medical Service, is placed on retired pay Surgeon General Jameson, whose term of office had not expired, relinquished his duties as head of the Army Medical Service at the end of last month, and official notice of his retirement is given in the *London Gazette* of June 4th It is confidently stated that Surgeon General W Taylor, C B, who is at present Surgeon General of His Majesty's Forces in India, will be, if he has not already been, recalled to this country We have previously expressed our opinion, which we see no reason for altering, regarding the absence of the name of the late Director General of the Army Medical Service in the list of those rewarded for their services in connexion with the present war in South Africa We are surprised that the excellent opportunity afforded by Surgeon General Jameson's retirement has not been seized upon The inclusion of Surgeon-General Jameson's name in the next big list of honours will hardly set matters right now that he has retired, and the slight which has been placed upon the Army Medical Service may be at this juncture most unfortunate. Everybody is anxious to know when Mr. Brodrick is going to appoint the promised committee of experts and what is to be done with the Army Medical Service. There are rumours of all kinds in abundance, but as far as we can ascertain nothing is really known of the War Minister's intentions. The state of uncertainty arising from the absence of any definite information may be considered detrimental to the interest of the public service; but Mr. Brodrick is in a situation where he can easily go wrong. Ill-advised interference on purely professional points may wreck an excellent scheme, and perhaps he is justified in being deliberate.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION OF ENGLAND AND WALES.

The annual meeting of this association will take place at the Trocadéro Restaurant, Piccadilly-circus, London, W., on Tuesday, June 18th, at 6 P.M. At 7 P.M. the members and their friends will dine together, Dr. R. Farquharson, M.P., President of the association, in the chair. Poor-law medical officers desiring to be present are requested to communicate with the honorary secretary, Dr. M. Greenwood, at 9, Copthall-avenue, London-wall, E.C. The price of the dinner will be 7*s.* 6*d.*, exclusive of wine.

SCARLET FEVER DUE TO INFECTED MILK.

Dr. George Newman, the medical officer of health of the borough of Finsbury, has recently issued a most interesting report upon an outbreak of scarlet fever in that borough which was due to infected milk. On May 7th there were notified nine cases, and between that date and May 14th 15 more. Upon receipt of the first notifications inquiries were set on foot and five out of the nine cases were found to have one feature in common—namely, that they had derived their milk-supply from a shop belonging to A. The milk was supplied to A by a contractor, B, who also supplied certain shops in Shoreditch and Bethnal Green. B in his turn derived his supplies from farms in Staffordshire and Derbyshire. B owned that certain milk which he had supplied to Bethnal Green and Shoreditch was suspected of having caused an outbreak of fever in those districts. He was certain, however, that none of this milk had been delivered in Finsbury. The milk in question had been obtained from a farmer named C, whose farm had been visited by Dr. W. H. Hamer on May 4th. Scarlet fever was found to be existing on this farm and the London County Council authorities accordingly informed B who at their request stopped the supply of milk from that farm. He knew nothing of the existence of scarlet fever until the Council informed him of it, and he admitted that he had no means of knowing whether or not there existed any infectious disease on the farms where his milk came from. On May 8th B called at the Finsbury Town Hall and informed the medical officer of health that he had made a mistake and that on the morning of May 3rd one churn, or possibly two churns, of milk from C's farm had been delivered to A. It was therefore evident that a certain quantity of infected milk had been distributed in the borough of Finsbury. 11 cases were traced to this milk obtained from A. Of the remaining 13 cases, in eight the milk was obtained from shops supplied by B. Two of the patients, whom we may call D and E, were infected in a somewhat curious manner. Their infection, says Dr. Newman, was evidently due to milk, and moreover to milk obtained on May 3rd. The milk in these cases was not got from A, but from another shop in J——road. Inquiries, however, elicited the fact that on May 3rd A's milk-boy when on his round met the milk-boy from J——road. This boy's supply had run short and he accordingly borrowed from A's supply. This supply contained milk from C's farm, a supply which was stopped shortly afterwards. The cases were all of a mild type, but, as Dr. Newman points out, the outbreak is instructive in so far as it shows how little real control there is over milk-supplies. Somebody buys milk brought to his door, which milk comes from a small shop supplied by a contractor who is again supplied by a number of farms. Purchaser, distributer, and contractor are all ignorant that the milk may be derived from a farm on which infectious disease exists. Dr. Newman considers that every contractor should keep a register of milk-shops to which the milk from every farm with which he deals is delivered, and secondly, that he should deal only with farmers who are willing to give a written guarantee that they will at once notify any outbreak of disease in man or animals upon their farms.

Lord Lister, F.R.S., will open the new operating theatres and children's ward at St. Thomas's Hospital on June 20th at 4 P.M. The theatres have been fitted with all the latest improvements for the carrying out of aseptic surgery and the new block of buildings is provided with an artificial system of ventilation. The children's ward is elaborately decorated with pictorial representations of fairy tales and nursery rhymes in tiles, the expense being defrayed by one of the governors of the hospital.

At an investiture held at St. James's Palace on June 3rd the recipients of the various honours in connexion with the operations in South Africa were introduced to the presence of the Sovereign when the King conferred their honours upon them. The names of the recipients who are members of the medical profession have already been printed in our columns.

The annual meeting and dinner of the Association of Public Vaccinators will take place at the Hotel Great Central on Friday, June 28th. Public vaccinators, whether members of the association or not, may obtain tickets for the dinner (price 7*s.* 6*d.*, exclusive of wines) on application to the honorary secretary, Mr. V. A. Jaynes, 157, Jamaica-road, S.E.

The death occurred on Saturday night (June 1st) of Dr. James Aitken Myrtle of Harrogate. Dr. Myrtle, who had practised in Harrogate for some 18 years, was at the time of his death holding for the second time the office of Mayor of Harrogate. We hope in a future issue to give a notice of his career.

A conversazione will be given by the West London Medico-Chirurgical Society on Friday, June 21st, at 8.30 P.M., in the Town-hall, Hammersmith, W., when Sir Richard Douglas Powell, Bart., K.C.V.O., will deliver the Cavendish Lecture, taking for his subject Acute Cardiac Failure.

We learn with great regret that Mr. Thomas Bond, F.R.C.S., consulting surgeon to the Westminster Hospital, committed suicide during an attack of mental aberration on Thursday morning by throwing himself from a third-floor window of his house in Broad Sanctuary.

Dr. R. Deane Sweeting, M.A. Oxon., medical inspector of the Local Government Board, has been appointed examiner in Public Health and Preventive Medicine in the University of Oxford.

The report of the Army Medical Department for 1899 was issued as a blue-book on June 4th. We shall deal with the report at length in a future issue.

THE LANCET

SPECIAL SUPPLEMENT

IN SUPPORT OF THE

METROPOLITAN HOSPITAL SUNDAY FUND

Published in aid of the Appeal to be made on Sunday, June 16th, 1901

OUR THEME IS EVER OLD AND EVER NEW.

IT has again become our duty to address the readers of THE LANCET, and that still larger public for which our annual Hospital Sunday Supplement is prepared, on the claims of the Metropolitan Hospitals to their sympathy and practical support We know that the subject has now become so familiar to our readers that it may be considered threadbare. This is, for example, the sixteenth time that we have published our appeal in aid of the Fund, and it is impossible that there can be many arguments left which plead in favour of generosity to the Fund which we have not already employed. For we have considered the matter from every aspect, and from each and all the claims of the hospital upon the public remain unaltered Our advocacy must necessarily be made on the same grounds from year to year. The poor have never such a right to ask their more fortunate neighbours for help as when they are sick; the hospitals exist for the succour of the sick poor; therefore it is the duty of all who can to assist the hospitals to the best of their ability. This must always be the gist of what we have to say, but the breadth of the questions involved in the matter is such that they cannot be dealt with exhaustively within the space of any one supplement. The social scheme, even in conservative England, is eternally altering, and in whatever way it changes such institutions as the Metropolitan Hospital Sunday Fund are sure to be affected by the variation

Of the many factors which obviously must operate one way or another for or against the finances of the Metropolitan Hospital Sunday Fund two are very general in their working, the whole nation is touched by them, and the Fund feels their influence. These are the fluctuations in population and the incidence of taxation, and to these we propose to refer this year somewhat at length.

LONDON LARGER THAN EVER.

The following table gives the population enumerated in 1901 at the recent census in the administrative county of London and in the 29 Metropolitan Boroughs:—

Population enumerated in 1901 in the Administrative County of London and in the 29 Metropolitan Boroughs.

Metropolitan boroughs.	Enumerated population, 1901	Metropolitan boroughs.	Enumerated population, 1901.
City of London ...	26,908	Lambeth	301,873
Battersea	168,896	Lewisham	127,460
Bermondsey	130,486	Paddington ..	143,954
Bethnal Green	129,681	Poplar	168,838
Camberwell	259,258	St Marylebone ..	133,329
Chelsea	73,656	St Pancras	235,234
Deptford	110,513	Shoreditch	118,705
Finsbury	101,476	Southwark	206,128
Fulham	137,289	Stepney	298,548
Greenwich	95,757	Stoke Newington	51,247
Hackney	219,288	Wandsworth	232,030
Hammersmith	112,245	Westminster, City of	182,977
Hampstead	81,902	Woolwich	117,165
Holborn	59,390		
Islington	334,928		
Kensington	176,623	Administrative County of London	4,536,034

The table is based upon summary returns furnished by the local registrars and must be regarded as provisional only, being subject to modification in detail when in due course the enumeration books have been received and scrutinised at the central office. But it is accurate enough for our purpose and shows that on April 1st in the present year the administrative county of London contained upwards of 300,000 more persons than lived in the same area one decade ago, 300,000 persons! Nearly the population of Bristol, and more than that of Bradford, Nottingham, and Newcastle has been added to the population of London since 1891. It is true that this increase falls short by 25 per cent. of the estimate of the statisticians, but the figure is quite large enough to make us pause, quite large enough to give thoughtful people material for contemplation when they remember that the great majority of the added thousands are poor persons who are compelled to some extent to look to charity for assistance in times of sickness. For the depletion of the country and the overcrowding of the towns consequent upon it still go on, and although we are glad to see by the figures that have been published by the Registrar-General that anticipation as to the extent of this transference of population has been belied, it will be some years before any real decentralizing movement will be felt. The increase of the population of London still goes on, and will go on. Hamlets become populous streets, populous streets connect one outlying urban district with another, and acre after acre of the environments of London becomes a solid mass of houses. The depletion of the country side is not so progressive as it has been, and the population of the metropolis at the recent census has fallen a little short of the estimated figure, but we must not for that reason lose sight of the fact that it has increased enormously during the decade. The unremunerative nature of work in the country—unremunerative because land-owners and tenants cannot afford to pay high wages when their produce finds so poor and so precarious a market—drives labourers to the cities; country life is terribly monotonous to an educated population, able by cheap methods of transit to obtain a view for themselves of the more stirring experiences of those who live in close contact with crowds of their fellows; the hopelessness of progression in the country is perceived by the more ambitious—a good ploughman remaining a good ploughman for ever, never having the slightest chance of rising above the position in which he was born, or of obtaining better wages at 40 years of age than he received when he was a lad with only himself to support. Born within a measurable distance of the workhouse of parents who, if he cannot succour them, will enter the workhouse, the agricultural-labourer can look forward very often to no better fate for himself than the workhouse. These things have combined all over England to make young men go to the towns. The fact is a sad one as well as a significant one, for they leave a healthy life for an unhealthy life, and 99 per cent. of them find that it is as difficult to progress in London as it is in the country, while higher wages are more than swallowed up by vastly higher expenses. There is, however, the hundredth chance. One man out of a hundred who leaves his village at the bottom of the social ladder may raise himself a step or two on the ladder, and, as it is the first step that counts, there is no reason why, having once started, he should not go quite high. For the sake of the hundredth chance the large towns have to cater for an enormous increase of population, a large proportion of which population lives in poverty; and of all large towns in the world none has attracted to itself such an overwhelming number of persons to whom illness may mean ruin as London.

STATISTICS OF HOSPITAL WORK IN LONDON DURING THE YEAR 1900.

TABLE I. — GENERAL HOSPITALS.*

* We reproduce the term "General Hospitals" as employed by the Council of the Metropolitan Hospital Sunday Fund.

Progress of the Metropolitan Hospital Sunday Fund.

The development of London has not been accompanied by any corresponding growth in the Metropolitan Hospital Sunday Fund. In point of fact, the annual collection shows no growth at all. From time to time the amount placed at the disposal of the Council of the Fund receives a welcome augmentation from the bounty of some private individual, but the sum collected in the churches was actually less in 1893 than in 1884, and had it not been for private munificence the Fund would have been sadly crippled in 1891, 1894, and notably 1895.

Progress of the Metropolitan Hospital Sunday Fund.

Year.	Totals.	Donations.	Year.	Totals.	Donations
1873	£27,700	£1844	1887	£40,607	£4130[4]
1874	29,936	1605	1888	40,379	3000

1884	39,329	6410[1]	1898	40,397	2817[13]
1885	34,320	2555[2]	1899	53,504	15,310[14]
1886	40,399	4817[3]	1900	51,993	14,657[15]

Let us take the collection of the Fund at its best and apportion it over the population of the metropolis. In 1890 the amount collected by offertory was nearly £39,000 and the population nearly 4,200,000, so that the average contribution of every individual would amount to something *less than* 2½*d.* For the purpose of this estimate it is assumed that only the County Council's London is interested in the hospitals of the metropolis. But that is very far from the fact. Outside the official boundary lies a densely populated zone inhabited by Londoners, although nominally appertaining to the adjacent rural districts, and to this area are extended in no small measure the benefits of the metropolitan hospital system. Were the population of Greater London taken into account for the purposes of our present estimate the modest figure would shrink considerably. *Let it*, however, suffice to assume, without refining upon the figures, that Londoners are prepared to support the great charitable work of their hospitals to the extent of an annual subscription of 2½*d.* a head. This is by no means [illegible] ng the result, [illegible] whatever kind [illegible] proportion to the number of heads would bear very unduly upon the poor, yet if, on the *other hand*, the benefits conferred by hospitals are considered, it will, of *course*, be found that these are in a preponderating measure realised by the most numerous and least wealthy classes of the community. The *families*, including children, *of the* poor are no less dependent than the families of the rich upon *medical attendance*, and to a very large extent in the case of poor people this necessity is supplied by hospitals. An estimate of population, therefore, affords the best means of realising how the benefits of the hospital service are distributed, for no class is excluded from these benefits; and when it is realised that the return made in the *form* of the Metropolitan Hospital Sunday Fund works out at something less than 2½*d.* a head it will, we think, be freely admitted that there is *good* reason for regarding it, not only as inadequate to the needs of the hospitals, but also as unworthy of the community which contributes it.

THE SMALL CONTRIBUTOR.

This is a view of the facts which should commend itself especially to persons of *moderate* or restricted means. To such the Metropolitan Hospital Sunday Fund affords a peculiarly *fit opportunity of tendering support to the medical charities* of London. A small subscription given in this way possesses both actually and sentimentally a value that it could not otherwise have. It is no small thing that the widow contributing *her mite upon this* occasion should *be able to feel* that it becomes *part* and *parcel of* a Fund large *enough to* form an indispensable part of the charitable revenues of this great city, and yet drawn almost entirely from sources such as her own benevolence has opened up. Thousands of *persons in London are so situated.* The subscription list with its regulation guinea is not for them, and were it not for the recurrence of the Fund collections they would stand quite aloof, wishing well to their suffering neighbours but being powerless to promote their well-being in any way.

It is from this class that the revenues of the Metropolitan Hospital Sunday Fund are chiefly drawn. Large contributions are the exception and rightly so. But we fear that *they will not remain the exception* unless the feeling *of the public that* to support the *hospitals* is an urgent obligation becomes more general. *For although the Fund* has claims upon the rich it has especial claims upon the poor, and the comparatively poor are so much the most numerous class that they preponderate by reason of their numbers, and *must so do as long* as the Fund continues to command the general confidence and support of the people at large. It would, indeed, be a sad day if the struggling many withdrew from the support of this charity. It is upon the sympathy of the many that any great undertaking must be built which, *like that advocated to-day*, requires ample and continuous pecuniary support.

THE NUMBER OF HOSPITALS AND MEDICAL CHARITIES IN LONDON.

The following is the *list of Hospitals* and Allied Charities to which awards were granted by the Metropolitan Hospital Sunday Fund in the year of the foundation of the Fund:—

List of Hospitals and Allied Charities which Obtained Awards in the First Year of the Fund (1873).

Belgrave Hospital for Children.
British Hospital for Skin Diseases, Great Marlborough-street, W.
Bromley Cottage Hospital.
Charing Cross Hospital.
Cancer Hospital, Brompton.
City of London Lying-in Hospital.
St Peter's Hospital for Stone.
City of London Hospital for Diseases of Chest, Victoria-park.
Dental Hospital, Leicester-square.
East London Hospital for Children.
Evelina Hospital
French Hospital.
German Hospital
Great Northern Hospital
General *Lying-in Hospital.*
Hospital of St. John and St. Elizabeth.
Hospital for Diseases of *Throat.*
Hospital for Women and Children
Hospital for Sick Children.
London Hospital
Homœopathic Hospital
University College Hospital.
North-Eastern Hospital for Children.
North London Hospital for Consumption.
Queen Charlotte's Lying-in Hospital.
Royal Orthopædic Hospital.
Royal South London Ophthalmic Hospital.
Royal Hospital for Diseases of the Chest.
National Hospital, Ventnor.
Middlesex Hospital.
Seamen's Hospital.
Samaritan Free Hospital.
St. George's Hospital.
Seaford Convalescent Home.
Victoria Hospital for Children.
West London Hospital.
Westminster Hospital.
Wimbledon Cottage Hospital.
Royal London Ophthalmic Hospital.
Royal Free Hospital.
Metropolitan Hospital.
Poplar Hospital
National Hospital for the Paralysed.
St Mark's Hospital.
British *Lying-in* Hospital.
Male Lock Hospital.
King's College Hospital.
Hospital for Women.
Female Lock Hospital.
Western Ophthalmic *Hospital.*
Hospital for Hip Diseases in Children.
Chelsea Dispensary.
Camberwell *Dispensary.*
City Dispensary.
City of London Dispensary.
Clapham General Dispensary.
Eastern Dispensary.
Finsbury Dispensary.
Farringdon General Dispensary.
North-West London Free Dispensary.
Haverstock Hill Dispensary.
Holloway Dispensary.
Islington Dispensary.
Islington *and North London* Provident Dispensary.
Kensington Dispensary.

If we compare this list wit[illegible] received awards last year we [illegible] long, for nearly 200 hospital [illegible] annually assisted by the Metro[illegible] This shows that the people of London have done a good deal to meet the stress continually thrown upon them by the increasing number of poor persons within their gates. Most of the new institutions are either special hospitals or charitable institutions auxiliary to hospital work, but in some degree or other all help to alleviate the misery of the sick poor. And that all are deserving of financial support may be taken for granted, for one of the great claims of the Metropolitan Hospital Sunday Fund to our consideration is that it represents order in our medical charities. It sifts the genuine charities from the imitation charities and has strong claims to support as an economic agency. While at present there is no great chance, in spite of considerable discussion of the subject, that such a Central Hospital Board as was once advocated by a Special Committee of the House of Lords will be created, the Council of the Metropolitan Hospital Sunday Fund have been in a position to accomplish much by way of suggestion and criticism to advance the interests of coöperation among the various charities. They have exercised a gentle but most salutary supervision over hospital expenditure, and by comparison and scrutiny have enforced the admirable doctrine that every pound of revenue should be represented by its equivalent in the form of service or of necessaries supplied to the objects of the charitable institution. In this way they have accomplished, and are [illegible] task that no private benefactor, however [illegible] abuse, could attempt. They speak with [illegible] numbers and are free from suspicion of [illegible] before the public, feeling generally well disposed towards the hospitals of London, cannot place their contributions in better hands. By delegating to the Metropolitan Hospital Sunday Fund the task of distribution they can avail themselves of a discretion perfected by collective knowledge to which no individual among them could hope to attain. With regard to the work of the Metropolitan Hospital Sunday Fund as an economic agency we are able to speak with particular clearness. We issue every year questions to the hospital authorities as to the number of in-patients admitted, the number discharged, the number relieved, the number cured, the number sent to convalescent homes, the number of individual out-patients seen, and the number of cases treated upon emergency. These questions have always been most fully and promptly answered by the hospital authorities, and from the statistical information thus obtained the various tables are prepared which will be found [illegible] seen [illegible] of [illegible] discrepancy would lead to further investigation. In this way

we arrive at the position of being able to speak with knowledge when we say that the Metropolitan Hospital Sunday Fund represents order in the distribution of charity.

We mention this because at the present time there is some doubt in the public mind as to which are the proper hospitals to support. The public are safe in following the lead of the Metropolitan Hospital Sunday Fund and of the Prince of Wales's Hospital Fund for London, the governing bodies of which make careful investigation into the administration of every single charity before recommending it for award. It is certain that many subscribers have ceased to support institutions which they thought did not sufficiently discriminate between the deserving poor and the designing well-to-do. Again, there have of recent years been disputes with regard to the management of hospitals which have been the cause of considerable apprehension among the public. There is an inquiry now going on into the merits of a quarrel between the medical staff and the lay administration of one admirable institution. The public may well feel that there is something wanting in the management of an institution where so bitter a quarrel can have raged for many years, and the feeling of mistrust that is thus engendered reacts to the disadvantage of other institutions where proper confidence bestowed upon the medical officers results in order and harmony. There is another factor which may damage the incomes of hospitals, though only to an infinitesimal extent, by increasing the mistrust engendered by faults of management. We refer to the abuse that is freely showered upon hospitals by certain cheap newspapers and certain self-advertising cranks. In the long run probably no harm is done to the institutions by either the scurrilous reporter or the mendacious anti-vivisectionist, but temporarily the hospital that is attacked may suffer. Its funds may be affected, when the self-constituted champions of the rights of the sick poor will have the melancholy satisfaction of knowing that they have added to the percentage of deaths due to lack of hospital treatment. Each of these things is new and helps to damage the hospitals of the metropolis. When we say to ourselves with some pride sixteen years ago there were only a hundred hospitals or so to be helped, and now there are two hundred, we should also realize that the hundred were helped in a less grudging spirit than the two hundred are now. We beg our readers to use their best endeavours to refute the silly charges of callousness and brutality that are brought by wrong-headed accusers against our noblest charities. No harm has been done as yet by these persons, but the medical mind perceives the absurdity of the attacks so clearly that it is apt to think that the public will also consider the matter beneath attention. The public may believe that if there were any substratum of truth in the stories that have been recently circulated with the set purpose of damaging the revenues of the hospitals we should inform them of it, however unpalatable that duty might be to us. And the public can subscribe with a free hand to the Metropolitan Hospital Sunday Fund and the Prince of Wales's Hospital Fund for London with the absolute assurance that in so doing their gifts will be properly meted out to deserving charities in equitable proportion.

The Costliness of the Modern Hospital.

It would be singular as well as singularly unfair if the hospitals of London at the beginning of the twentieth century should lose the support and confidence of the public for whose good they have been founded. The hospital of to-day is a very different institution to the hospital of 100 years ago, and also to the hospital of 16 years ago. Its value to the community is incalculably greater, while its cost of maintenance is also very much higher. One hundred years ago the hospitals of London were not the centres of medical thought, medical progress, and medical education that they are now. Undoubtedly they did an enormous amount of good, but their value was much impaired by the methods of administration of the day. Neither the honorary appointments nor the resident appointments were held by gentlemen who owed their positions on the staffs to pure merit. Many excellent surgeons and excellent physicians, in fact the leaders of nineteenth century medicine, were upon those staffs, but there were others who had an equal share in the treatment of the sick who were not dowered in a similarly fortunate manner with scientific skill and insight. As a consequence the patients in the hospital were not so absolutely certain as they are now of receiving treatment which is truly representative of the high-water mark of medicine. Again, the nursing in the hospitals in the days when Abernethy and Cooper flourished was not what nowadays would be considered nursing at all. Surgeons were attended by their own assistants and dressers, whose work done under their master's eye was as a rule competent and sometimes excellent, but the women upon whom the ordinary ministrations to the patients devolved were for the most part devoid of training. All the culinary arrangements of the hospitals 100 years ago were of the crudest, and the diet was so little regarded as an adjunct to treatment that hawkers were permitted to enter the wards and sell delicacies to the patients. It is not within our scope here to describe how these various abuses disappeared. Scandalous mismanagement gave way largely to the fierce searchlight thrown by The Lancet upon the domestic affairs of some of the most famous institutions in the kingdom. The wider knowledge of public health made it obvious that the environment of the patient, the ventilation of the wards, the cooking of food, and the ministration of nurses were almost as important as the direct diagnosis of his condition. Then, and so much more recently as to be almost coincident with the foundation of the Metropolitan Hospital Sunday Fund, came antiseptic surgery. Remember the necessities immediately entailed in the matter of reconstruction of operating theatres, the re-stocking of instrument cases, in short, the reorganization of the surgical side of the hospital. Hard on the heels of antiseptic surgery came the developments of physiology and bacteriology, making the study of the natural history of disease an integral part not only of medical education among the students but of medical practice among the staff and routine among the nurses.

These words suffice to roughly indicate why the cost of maintenance of the big general hospitals of London has increased so enormously. In the meantime, what of their incomes? It would be thought that as they did more work, as they passed out of their wards a higher percentage and a steadily rising higher percentage each year of convalescents, they would meet with wider recognition from the public. They have not done so, while the public for which they cater has increased out of all proportion to the size of the subscriptions to the institutions Attempts have been made to show that money subscribed for the needs of the sick has in certain hospitals been perverted to the use of lecturers and students, feverish in the cause of experimental science—as though it was only the cost of medical education that had risen with the development of science and not the cost of medical treatment Everyone who is really cognizant of what the administration of a big London hospital means knows that all the funds received, whether the money is spent upon buildings or food, upon salaries or drugs, upon instruments, or even upon rates, are devoted to the welfare of the patients. Rates must be settled lest the civil authorities take resentful action; medical students must be trained, or who will take charge of the sick of the future? Clerks must be paid, drugs must be purchased. In no large hospital in London is the expenditure regulated by anything else than the honest endeavour to get as much good out of the money as possible for the sick poor; and if some of the smaller hospitals have not always been so disinterested in their origins or careers, we may rest assured that the fact is well known to the distributing bodies of the Metropolitan Hospital Sunday Fund and the Prince of Wales's Hospital Fund for London, and that the institutions in question have their reward.

The Incidence of Taxation following the War

The particular feature of the first collection in behalf of the Metropolitan Hospital Sunday Fund made in the new century is that it has to be made in the teeth of heavy taxation laid upon the country to meet the enormous cost of a protracted war. The incidence of taxation does not as a rule influence the receipts of hospitals much, and we may hope that it will not do so during those years through which the Government of the country may think it necessary to maintain the war tax Undoubtedly, a big income-tax weighs heavily upon a very large class of citizens, and just that class which, in London, might well be expected to lend substantial support to the finances of hospitals. We refer to persons having incomes ranging from £500 to £1500 per annum. These are the persons who, while the income-tax is maintained at its present figure, may, in their anxiety to curtail their expenditure, cut off their subscriptions to charity. They are, many of them, professional men and well-paid employés, and to a great extent their income is dependent upon their expenditure. If they paid less rent they would receive lower fees;

if they lived at a greater distance from their work they would not be such valuable servants. Their appearance of com- [illegible] for they are only stewards of [illegible] it with [illegible] to them, [illegible] so small. But we trust that the middle-classes will continue to support the Fund which, of all charities in London, does the most for [illegible] will when their [illegible] side as well they [illegible] withhold as fr[illegible] subscriptions from the hospitals, either direct contributions to particular institutions or indirect contributions through the medium of the Metropolitan Hospital Sunday Fund, because the South African war has brought expenses in its train is to make the poor suffer for the cause of Imperial expansion, which they have only endorsed to the same degree as it has been endorsed by their social superiors. We trust that the vicarious patriotism which pays the exactions of a protracted war by cutting off subscriptions to charities will find no place among our readers. For the war should furnish the most convincing reason imaginable for increasing our individual efforts to place the hospitals of the metropolis in an efficient condition. It has brought in its train much misery. The people of the country have been open-handed in their attempts to avert the inevitable concomitants of war; praiseworthy efforts to mitigate the lot of those whose fathers, husbands, and sons are fighting, or perchance have fallen, on the veldt have been organised in every direction All such eleemosynary work is tributary to hospital work, for the sequel of hunger is sickness, and the bourne of sickness is the hospital. But in spite of the splendid and devoted labour of many of the most highly-placed persons in the land there must be much misery consequent upon the prolonged absence from home of so many thousands of our compatriots. There should be no wards closed in the metropolitan hospitals while there is a chance of anyone dependent upon a soldier for bread requiring a sick bed Alas, some of the largest and most important of our general hospitals are compelled to cripple their efficiency, for to attempt to accommodate the number of sick which should find shelter in their walls would simply mean bankruptcy. This should not be.

Between the well-to-do and the genuine poor, who are, under all circumstances, proper subjects for hospital treatment, there comes an enormously large class who might be expected to increase their subscriptions to the Metropolitan Hospital Fund or other charities in recognition of the fact that the cost of the war has not fallen quite so heavily upon them as it has upon the class that is in a sense much richer than they are Those upon whom the income-tax does not fall are obviously poorer than those who have to pay it, but they are a class for whom the State has of recent years, and quite rightly, strained every nerve, and a class who have become comparatively better off because of their freedom from the taxation to which those richer than themselves are subjected The earners of good wages in good employ have been looked to by each of the great political parties alike for support, and have received favours from each. The Education Acts, the Workmen's Compensation Act, the Employers' Liability Act, the Friendly Societies Acts, and the legal recognition of trade unions have raised the operative of Great Britain to a position which he has earned by his sterling qualities and which no other European country has been able to grant him. In times of national trouble—and the South African War is a national trouble—he may be expected to remember this And he cannot show his consciousness of having received fair treatment from his fellow men better than by supporting, to the best of his ability, charities of such a truly national character as the voluntary hospitals of London. If every pound that is lost from the richer class is made up to the hospitals by the receipt of twenty shillings from the poorer the hospitals will not only be no losers but, paradoxical though it may seem, they will be gainers For man is an imitative animal, and twenty new subscribers of a shilling afford twenty examples who may well be followed, and a certain proportion of whom will be followed And it should be remembered that the class of which we are now speaking are largely benefited by hospitals. For minor ills they may employ their private medical man, they belong to clubs—many of

them whether their scale of pay warrants their obtaining medical assistance upon cooperative terms or not—and receive from the club medical officer attention in what may be termed the routine diseases that flesh is heir to; but when their case becomes really serious, when a bad accident prostrates them, when a fever requiring lengthened treatment and adequate nursing attacks them, or when a major operation has to be performed upon them to save life or render the damaged system a sound one, then they must have recourse to hospitals.

The most marked feature of this year's Hospital Sunday collection is that it follows closely upon a Budget which must make a severe demand upon slender purses. We trust that no one will allow the fact that he has to pay his share of the bill for the South African war to sway him in making a smaller contribution than is his wont to the Metropolitan Hospital Sunday Fund. The money was never more urgently wanted by the hospitals than now, when the country is suffering from the effects of the war.

ALL MUST HELP.

Such is our appeal on behalf of the Metropolitan Hospital Sunday Fund for the first year of the new century. The population of London is increasing by leaps and bounds, which every year makes the metropolis more distinctly the centre to which the empire resorts, so that the institutions of London are regarded as serving the necessities of a world rather than of a city. But while the population of London becomes larger the income of the Metropolitan Hospital Sunday Fund, as far as it is drawn from the people rather than from individual donors of big sums, remains stationary. Ten years ago the inhabitants of London paid a sum equivalent to 2½*d.* per head as their subscription to the Fund, and since then the capitation contribution has decreased, although the number of reputable institutions to be supported is much larger, while the cost of hospital administration is heavier in every respect. These facts we have stated perhaps somewhat boldly, but we have purposely directed our appeal this year rather towards the reason than towards the sentiment of our readers. We have taken it for granted that no words are necessary to bring home to our readers the terrible misery which sickness means to the poor man and poor woman. The incapacity of the bread-winner to earn his wages at once places the family of the poor man within a measurable distance of starvation. That little distance would be immediately crossed if the hospital did not open its doors to the sufferer. And now a time has arrived when many beds are closed and many of these unfortunate people have to be refused the shelter which means so much to them and so much, perhaps as much, to their families. It is the lives of the poor for which we are pleading.

The rich should give out of their superfluity, and not only because they are rich, but because they are themselves directly benefited by the hospitals. For without our hospitals the benefits which the rich derive from skilled medical attendance could not be theirs.

The poor should give out of their poverty, and they need no reminding as to what the hospital means to them when they are sick. But they need much reminding as to the value of little gifts, or the Metropolitan Hospital Sunday Fund would not stand at the annual figure of £40,000. If there are half a million persons in London to whom an annual subscription of 1*d.* is impossible there must be at least 2,000,000 others who are poor in that they are living on their wages, who could still afford an annual gift of 1*s.* If they gave that shilling each year the hospitals would soon be placed well on their way to freedom from debt.

To the benevolent man no scheme can commend itself as more worthy of his assistance than a fund to benefit his suffering and poorer brethren.

In the eyes of the practical man no less than in those of the benevolent the Fund should, nay, must, find favour, for it represents order in the distribution of charity.

To all social grades, to all creeds, and to all casts of thought, the Metropolitan Hospital Sunday Fund must appear as a noble charity, splendidly directed, economically managed, and equitably administered. That it may meet with support worthy of its merits is our most earnest hope.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

Audited and found correct, this 27th day of November, 1900.

(Signed) W. H. PANNELL & Co, *Chartered Accountants,* 13, Basinghall street, E.C.

*** In the preparation of the voluminous statistics of hospital work which have been here digested and exhibited in collected form (and which have been specially supplied to us in response to our applications, and are quite independent of any returns made to the Metropolitan Hospital Sunday Fund Committee) we have been greatly indebted to a large number of secretaries and other officers of the various medical charities of the metropolis. To them we desire, as on many previous occasions, to tender our sincere thanks.—ED. L.

Printed and Published by the REGISTERED PROPRIETORS of THE LANCET, at 423, Strand, W.C., and Nos. 1 and 2, Bedford-street, Strand, adjoining

EXPERIMENTS ON LIVING ANIMALS.

THE inspector's report for the year 1900 has just been issued and is on the same lines as those of the last decade or so The total number of experiments of all kinds appear to have been 10,839, of which 8954 were inoculations or similar trivial proceedings performed without anæsthetics. The fact that so many experiments are performed "without anæsthetics" is made the most of by platform humanitarians as evidence of unheard of cruelty, but a reference to the inspector's report will show that, whether or not any of the inoculated animals suffer, pain is entirely a matter of speculation. The platform humanitarian does not, as a rule, give himself the trouble to go and see inoculated animals for himself but is content to trumpet inoculations as an atrocity to which vaccination is in no sense comparable. Readers of THE LANCET will know that it is seldom possible to say whether or not an animal has been subjected to inoculation, and that when the inoculated and non inoculated are kept in the same cage it is, as a rule, only the label which distinguishes them. Certain London hospitals have recently been accused of using charitable funds for the purpose of vivisection, and if, for the sake of argument, we accept these statements we are able to judge, by the tables in this report, of the amount of money which has been spent upon living animals by these institutions At the medical school attached to one of the hospitals which has been gibbetted by the platform humanitarian we find that there are two licensees who performed experiments in 1900 One of these gentlemen performed three experiments under anæsthetics for lecture room purposes The animal was anæsthetised and there was therefore no cruelty. The expense of these experiments could not have been more than 10*s* or 12*s*. and the money certainly came out of the licensee's pocket or possibly that of the treasurer of the school The other gentleman used 108 animals for inoculations or similar proceedings These animals were not horses, dogs, cats, asses, or mules, and we are probably correct in assuming that they were rodents (rabbits, guinea-pigs, rats, and mice). These animals cannot have cost more than, perhaps, a £10 note.

At another institution which has been selected for condemnation there is one licensee who performed 158 experiments, of which 94 are definitely stated to have been inoculations for purposes of diagnosis, and, assuming that the animals used were rodents, we may take the expense at less than £20 The animals used for the whole of the experiments tabulated at all the institutions in the country can scarcely have cost as much as £1000, which is very much less than the sum mentioned as spent upon vivisection by four of the London hospitals.

We will not enter into the question as to whether the cost of any of the animals used has been defrayed by funds supplied by the public, but we are of opinion that all would admit that the use of animals for diagnosis is a necessary prelude to medical treatment and that the cost may legitimately be defrayed from funds contributed for the benefit of the sick When the Vivisection Act was passed in 1876 it was regarded as an extension of the Cruelty to Animals Act to scientific research, and there can be no doubt that by those who framed it inoculation was not contemplated and that the phrase "calculated to give pain" was intended to be interpreted in a common-sense way. Nobody objects to the control of experiments which involve serious surgical operations, but the inclusion among "vivisections" of inoculations made for purposes of diagnosis or research has been a calamity for British medicine. If a modern practitioner in a remote village were to inoculate a guinea pig with the pus from a doubtful case of plague for the sake of accurate diagnosis it is very unlikely that any jury would convict him of cruelty to animals The practice of inoculating a donkey for the purpose of diagnosing glanders existed for years before the passing of the Act and was never regarded as an act of cruelty punishable by law.

The inspector in his report says (p 5):—

> There is, however, strong (*sic*) reason for holding that the gradual development of tuberculosis and the poisoning by diphtheria toxin resulting from such inoculations, although they may not be accompanied by acute suffering, are conditions which bring these proceedings within the category of "experiments calculated to give pain."

The inspector does not furnish any facts which would serve as evidence in a court of law that an inoculated animal was cruelly suffering. Most of the infective toxins dim the sensibilities as much as do anæsthetics The First Lord of the Treasury in a recent address told his audience that English medicine was not in the forefront and asked what was the cause of it. The reason for this backwardness is furnished by this report, which seems to show that his colleague at the Home Office is ready to strain an Act of Parliament for the sake of worrying honest investigators. We are very much in want of a Minister who will look into this matter for himself and will not yield to the clamour of those who raise the cheap cry of humanity and throw mud at the leaders of a noble profession The extent to which licensees are worried when under the Act is shown by the closing paragraphs of the report which constitute a sort of small-beer chronicle of offences which are scarcely sufficiently heinous to render them worthy of being presented to Parliament. We will give one instance.

The inspector says —

> I have had to report the following irregularities 1 A licensee holding the certificate dispensing with the use of anæsthetics performed some inoculations under anæsthetics, allowing the animals to recover therefrom The animals suffered no pain. This is an irregularity, because the certificate (B) required by the Act when an anæsthetic is used, and the animal allowed to recover therefrom, is different from the certificate (A.) required when an experiment is performed entirely without anæsthetics

We do not blame the inspector for reporting this, even assuming that he is a free agent as to what shall and what shall not appear in his report. It is interesting as showing what an Act of Parliament means. This offence, if we remember right, has been reported previously and the humanitarians who are strangely ignorant of law when it suits their convenience, pointed to this strict administration of the law as evidence that the use of anæsthetics was positively disallowed by the Home Office ogres whose minds were said to be set on cruelty.

ROYAL MEDICAL BENEVOLENT COLLEGE, EPSOM.

A MEETING of the Governors of the Royal Medical Benevolent College, Epsom, was held on May 31st under the chairmanship of the treasurer, Dr. Constantine Holman, at 37, Soho square, London, W. The report of the council was read by Mr. J. B Lamb, the secretary, and it stated that His Majesty the King had been pleased to become the patron of the college. The late Mr. John Frederick France, a former member of the council, had left half of the residue of his estate, amounting to £10,000, to the pension fund of the college for the benefit of aged and necessitous members of the medical profession to be chosen by the council. From various reasons the year 1900 ended with a debt of £2500 There were on the college books at that time nine Pugh pensioners, 46 ordinary pensioners, two Morgan annuitants, and two Da Silva pensioners A festival dinner in aid of the funds for the pensioners and foundation scholars was to be held on July 9th, at which the Earl of Rosebery, the President of the college, had consented to be present The Forest Exhibition was awarded last year to J. E. Freeman. The hospital scholarships were won as follows · St Bartholomew's, C. H. Cross; Charing Cross, L H. Booth; University College (and the Carr Exhibition which goes with it), J. M. O'Meara; St Mary's, W. A. Owen; St Thomas's, D. Wilson; Middlesex, H R. Vivian; Westminster, C J E Bennett; and London, E L. Sandiland. The Jenks Memorial Scholarship was given to A. G. Sworn.

The CHAIRMAN, in moving the adoption of the report, pointed out that if the debt were not paid off the effect would be to cripple the work of the college for some time. He had hoped for some years that it would be possible to capitalise such a sum as £100,000 so that they might do away with the wretched system of begging The institution was called the "Royal Medical Benevolent College" and it was founded to help the medical profession; but it was not purely medical—they wanted to attract within its walls other than medical men because a mixed school was best. The use of the word "benevolent" had brought about in certain minds the idea that the college was a charity school. It was no more a charity school than Winchester or Eton or any other of the great public schools with a foundation. Referring to the letter published in THE LANCET of May 18th, p. 1428, in which "An Old Governor" says that "the recommendation committee, as in many former years, entirely ignores the men," the chairman remarked that he would not take more notice of the letter than to point out that it was only the committee of selection that could possibly know the facts and he had never met with a more painstaking committee: sometimes the lists of candidates were gone over as many as four times and this he had seen himself.

Mr. CHRISTOPHER HEATH asked who was the successful candidate to the last vacancy for St. Anne's as he had never seen any public notice of the election. Upon being informed that the election made was never published Mr. Heath said that he was surprised and then proceeded to remark that he rather sympathised with the writer of the letter in THE LANCET in regard to the widows being looked after while the unfortunate practitioners went to the wall. It seemed rather hard that a man should go on applying for a pension for nine years and then not get it. If he (Mr. Heath) were near the age of 79 years he would under the circumstances of the case consider that he was entitled to some assistance, particularly if he had asked for it so many times as the candidate had. In the list published by the council, concerning which Mr. Heath had no fault to find, he noticed that Mr. George Hodges had received 1286 votes, so that his case could not be a very bad one. He hoped the committee would take the case into consideration next time and see if they could not give Mr. Hodges a pension. Mr. Heath concluded his remarks by assuring the council that he was not complaining in any way, he was only anxious that the claims of the practitioners should not be overlooked.

Mr. S. FELOE, in seconding the motion, defended the action of the committee of selection and said that the claims of the few men would of necessity soon be satisfied because, as the chairman had announced, Mr. France had left £10,000 for that purpose.

After some formal resolutions had been passed a vote of thanks, on the motion of Sir JOSEPH FAYRER, to the chairman was adopted.

The following is a list of the successful and unsuccessful candidates for pensions and foundation scholarships at the election declared at the meeting:—

PENSIONERS.

SUCCESSFUL CANDIDATES.

1.	Eliza F. Chapman	10,238	3.	Ellen Bull	7141
2.	Fanny A. Coleman	8713	4.	Charlotte E. Davies	6616

UNSUCCESSFUL CANDIDATES.

5.	Alice M. Richardson	4770	13.	Lucy E Matthews	388
6.	Mary F. Freshfield	3474	14.	Francis D. Hamilton	333
7.	Ellen L. O Stevens	2193	15.	Margaret M. Sheppard	316
8.	George Hodges	1286	16.	Fanny W. Wilson	315
9.	Charlotte Johnson	1101	17.	Frances Newsam	200
10.	Thomas B. Whitehead	765	18.	William Hopkins	190
11.	Fanny E. Owen	747	19.	Eliezer Williams (deceased)	
12.	Eliza Clarke	572			

FOUNDATION SCHOLARS.

SUCCESSFUL CANDIDATES.

1.	Graham A. L. Anderson	10,939	4.	William Bourne	6644
2.	Clifford A. Mallam	9475	5.	Geoffrey W. Adams	6189
3.	Arthur R. Hemsted	6897	6.	Thomas G M. Clarke	6168
			7.	David A Buchan	5427

UNSUCCESSFUL CANDIDATES.

8.	Cyril J. P. Martin	3539	17.	James L Taylor	787
9.	Gerald K. MacNaught	2424	18.	Wilfred L. Corry	700
10.	John H. Sewart	2303	19	Eric S Monro	642
11.	John A Cowan	1507	20.	Harry P. Snell	555
12.	Harold D. Wilson	1288	21.	Albert H. Fleming	546
13.	Reginald H. Leigh	1081	22	Sydney D. Newton	465
14.	William T. K. Wallington	1080	23.	John A. R. Campbell	390
15	Douglas Hamilton	1048	24.	Edward Cooke	344
16.	Hugh L G. Hughes	872	25	Alan R. W. Paul	287

THE MEDICAL DEFENCE UNION.

THE annual general meeting of the Medical Defence Union was held at the registered offices, 4, Trafalgar-square, London, W.C., on May 31st. The chair was occupied by the President, Dr. W. S. A. GRIFFITH. The number of members present was at the beginning of the meeting about 20, but it increased to over 40.

The report of the council upon the work of the Union during 1900 showed an increased membership amounting to 4604. The number of cases dealt with by the council had increased, but the number taken into court had decreased. The rule of the council was "never compromise an action," as it had been found that when legal proceedings had been taken against a member of the Union and had been defended by the solicitor the case had been carried on up to, and sometimes almost up to, the moment of trial and had then been dropped. It was now recognised that when a member of the Medical Defence Union was to be defended by their solicitor no compromise would be suggested or agreed to but that the case must be run or dropped by the attacking party. Any attempt to blackmail or to extort money by threats was instantly dealt with by the Union with all the resources of the law and in no instance unsuccessfully. In such cases no temporising or weakness must be shown—the attack must be made on the enemy's camp, and such attacks must be sudden and decisive. The only possible source of danger was when the member involved had, through weakness, not reported the matter at once but had attempted to deal with it himself or by friends not versed in the art of active warfare. The most veiled attack on a man's character and professional honour if allowed to pass might become more open and pronounced in time and would be then difficult to "scotch"; if dealt with at once it was easy to destroy or to avert. Many hundreds of cases were brought before the council at the regular monthly meetings, or at the committee, or at the emergency meetings when required. During the course of the year it had been found necessary to revise the standing orders which were somewhat out of date. One of the many sub-committees had recommended that a representation should be made to the General Medical Council to the effect that it was desirable in the interests of the public that registered medical practitioners either individually or collectively by association should not be allowed to issue any document which in any way could be taken by the holder or the public as granting authority to practise or which could be used to cover any practice of medicine, surgery, or midwifery, saving in the case of persons examined by duly appointed examining bodies under the supervision of the General Medical Council. This sub-committee also reported that with regard to the practice of midwifery and diseases of women midwives were supported in their said practice by documents issued by lying-in institutions and societies of medical practitioners. The council of the Royal British Nurses' Association of London had been informed by the Medical Defence Union that the words "qualifying" and "diploma" were objectionable and likely to mislead the public into the belief that the nurses who in the Register were marked as having obtained certificates from the London Obstetrical Society were registered practitioners in medicine or surgery or midwifery. In one case of unqualified practice an absolutely unqualified person was found practising medicine in a country village, giving himself out as possessing better qualifications than the local medical men. He was fined £5 for using registrable titles in signing a certificate of death, but he continued to practise. The Medical Defence Union prosecuted him under the Medical Act and he was again fined, and this had the desired effect of making the offender cease practising. From pages 18 to 31 the report was taken up by a schedule of cases selected from the minute-book which constituted an excellent record of the useful work of the Union. Mr. W. E. Hempson, the solicitor to the Union, contributed a valuable statement of the legal work during the past year. The Lunacy Commissioners had shown an unwonted vigilance in prosecuting medical men for receiving and treating for remuneration patients alleged by the Commissioners to be certifiable. The condition of affairs was under the circumstances somewhat illogical and embarrassing and the risk was not confined to the medical man but would apply equally to the proprietor of an hotel or a boarding-house. Mr. Hempson suggested that the difficulty might be met by an alteration in the law.

The report of the Council for the year 1900 was formally moved by the PRESIDENT and seconded by Mr. S. FELOE. After some discussion, in which Dr. E. D. VINRACE, Dr. WALTER SMITH, and Mr. P. ROSE took part, the motion was carried unanimously.

The accounts as audited by Mr. Hardy were passed on the motion of Mr. M. A. MESSITER after being duly seconded.

Dr. Langley Brown, Mr. J. Roche Lynch, and Mr. M. Hallwright were elected members of council.

The sum of £100 was voted *pro rata* to the provincial members of the council as payment of railway fares when attending council meetings

Mr L Hardy, F C A, was re elected auditor and with the usual vote of thanks to the chairman the proceedings terminated

THE MEDICAL, SURGICAL, AND HYGIENIC EXHIBITION

(Concluded from p 1565)

The exhibition of sanitary appliances was a decided feature this year Leading pottery manufacturers were well represented, their exhibits consisting generally of sanitary fittings designed for use in hospitals and of improved sanitary appliances connected with the bath, lavatory, and water closet The exhibit of Messrs Doulton and Co (Lambeth, London, S E) was made specially attractive and medical men in particular studied the new designs of sanitary fittings with interest Amongst these were a white vitreous enamelled operating table fixed on a centre pedestal and so arranged that it could be moved to any position, a bed pan and urine bottle sink in strong white glazed ware provided with an air tight glass cover and a sterilising steam jet, the whole being worked by means of treadles, a sink for bed pans conveniently shaped and with treadle action for flushing, a strong white glazed ware closet fixed on brackets and clear of the floor, provided with a vulcanised seat and a pottery cistern Besides these an earthenware lavatory was shown with basin and top in one piece for operating rooms and supported on brackets As will be seen, the chief points about these excellent sanitary apparatus were the treadle arrangements for controlling the water supply, leaving the hands quite free, and the fixing of sinks and closets on brackets and quite clear of the floor By giving attention to these points great sanitary advantages are obviously gained Illustrations of similar advances in the construction of sanitary appliances were shown by Messrs G
road, London, S E
sinks, and closets
exhibit comprised also some excellent designs in bath and closet fittings, the former provided with a chair seat, sitz jet, and spray, and the latter with hot and cold shower, wave, douche, needle, and sitz sprays Worthy of mention also are the concealed and combination lavatory appliances and an improved bed pan flusher arranged especially for the disinfection and sterilisation of excreta Pedal action lavatories and cantilever bracket water closets formed the chief examples of sanitary advance at the attractive exhibit of Messrs J Tylor and Sons (2 Newgate street, London, E C) The pedal action is a decided advantage and the pedals being hinged may be lifted clear of the floor for cleaning In the same way the water-closet is supported on galvanised cast iron cantilevers built into the wall so that the space beneath the closet is clear and the floor and fittings may easily be kept scrupulously clean

Disinfectants and means
important section of the
Sons (146 and 147, Houn
illustrated the Equifex steam disinfectant appliances, and at the same stall Pasteur filters were shown working with and without pressure for domestic, travelling, industrial, and technical purposes Messrs Boake, Roberts and Co (Stratford, Essex) illustrated the advantages of liquid sulphur dioxide for fumigation and disinfectant purposes Liquid SO_2 may be obtained in hermetically sealed tins, holding 12 and 20 ounces of the liquid, larger quantities may be obtained in glass and steel bottles and in copper cylinders The exhibit included a fluid preparation of phenol called "lozar" The same preparation may be obtained in the form of powder, which consists of a light wood fibre containing from 5 to 25 per cent of lozar An enormous variety of sanitary preparations were displayed on the stall of the Jeyes' Sanitary Compound Company (54, Cannon street, London, E C), including medical soaps, toilet soaps, disinfectant fluid, and surgical dressings The now well known Kieselguhr filter of the Berkefeld Filter Company (131, Oxford street, London, W) was illustrated in its various applications at the stall of the company Careful investigation has shown that the filter is a germ proof filter, and it has been used for supplying sterilised water of regulated temperature for surgical purposes Izal (Newton Chambers and Co, 331, Gray's inn road, London, W C) is now applied for a variety of purposes It offers the very important advantage of being, comparatively speaking, non poisonous Besides izal soaps, medical izal, lozenges, ointments, &c, izal is also used as an antiseptic for lint, wool, and gauze The Dowsing Radiant Heat and Light treatment was illustrated by the company bearing that name (24, Budge row, Cannon-street, London, E C), the electric illumination serving to attract many of the visitors Messrs Ewart and Son (346, Euston road, London, N W) exhibited a number of geysers of varying size for the instant production of hot or boiling water We are glad to note in connexion with these appliances that an efficient flue pipe is attached provided with a safety socket The only exhibit illustrating induced ventilation was that of Messrs James Keith and Blackman (27, Farringdon avenue, London, E C) Several Blackman fans were electrically driven in various parts of the hall for improving the ventilation. Some attention was given to the exhibition of special clothing Thus, amongst the indiarubber goods of Messrs Anderson, Anderson, and Anderson (37, Queen Victoria street London, E C) were improved operation aprons and sleeves and germ proof clothing for use in infectious cases Close by were interesting specimens of Aertex cellular clothing of the Cellular Clothing Company, Limited (72 and 73, Fore street, London, E C) This cloth is porous and a non conductor of heat All kinds of wearing apparel are made of this material, which is said to be easily washed and unshrinkable Cotton wool underclothing was the special subject of exhibition by the Lahmann Agency (15 Fore street, London, E C) It is described as "reform underclothing," and many important claims are made in favour of this material for underwear

Surgical appliances did not form a very large feature of the exhibition, surgical bandages and similar materials being brought more into prominence than surgical instruments Mr Vincent Wood (Victor House, 4, Albion place, Blackfriars, London, S E), exhibited a great number of bandages for various purposes and elastic hosiery The exhibit included the eureka cellular hygienic bandage and the crêpe velpeau bandage, the latter a rubberless elastic material porous and washable The Sanit
Limited (26, Thavies Inn, Holbo
exhibited many applications of
Wool preparations, as, for example, wood wool sheets for accouchement, wood wool vaccination pads, and wadding and tissue The exhibit included also the handy and convenient patent sling by Hartmann which we have already described in our "New Invention" column The improved instep arch sock for the treatment of flat foot was amongst the interesting appliances shown by Mr Thomas Holland (40, South Audley street, Grosvenor-square London, W) He also exhibited a "bunion splint patent" for restoring the big toe to its natural position It consists of a thin and flexible sole of leather divided at the toe end and fitted with a glove like pocket into which the big toe is inserted It certainly keeps the big toe in position, but the object of this patent would be obviously defeated by wearing badly fitting boots The patent appliances for the lame of the O'Connor Extension Company (2, Bloomsbury street, London, W C) are too well known to need description The exhibit included, besides the O Connor extension boot, a patent surgical boot compensating for a slight shortening of the leg, a boot for flat foot, a toe raising boot, a boot for paralysis, and a boot for talipes varus and valgus The Domen Belts Company (456, Strand, London, W C) exhibited their well known abdominal belts and corsets, both giving support without undue pressure Surgical instruments were well represented in their relation to modern surgery by Messrs Down Brothers (St Thomas's street, London, S E), while Mr W K Stacy (19 Newgate street, London, E C) showed some ingeniously designed nurses' bags and aluminium wallets X ray apparatus in working order was shown by Harry W Cox, Limited (10, 11, and 28, Cursitor street, Chancery lane, London, W C), who have supplied x ray coils and apparatus to the Admiralty and to the War Office for use in South Africa The fact that the winding and insulation of these coils is personally supervised is a guarantee against their breaking down Messrs A Rosenberg and Co (21, Southampton row, Holborn, London, W C)

also take especial care in the manufacture of induction coils for x-ray work. Their new patent portable x-ray outfit is worth attention by those who want such an apparatus for field and professional requirements.

Aerated waters and other beverages were not much in evidence. Messrs. Cooper and Co. (Gloucester-road, South Kensington, London, W.) had an excellent array of their oxycarbonated waters in syphons. We have previously pointed out that the effect of mixing oxygen with a carbonated water is very pleasant—the taste is soft and attractively fresh. The water is distilled and very pure. Medicinal waters are also made with oxycarbonated water—containing, for instance, lithia, fluid magnesia, piperazine, or other drugs. The Dry Wine Co. (104, Great Portland-street, London, W.) exhibited a natural spring table water drawn from springs near Homburg, the water being known as Cambrunnen Table Water. The exhibit also included "Vinzoe" wine—a tonic wine the basis of which is a good dry sherry to which the nutritives of beef are added. Messrs. Stephen Smith and Co. (Malmesbury-road, Bow, London, E.) submitted for inspection Hall's coca wine and Keystone burgundy and Keystone beef wine, each of which has been dealt with in our analytical columns. Messrs. Marshall and Elvy (45, New Oxford-street, London, W.C.) exhibited specimens of an excellent Cognac brandy (Courvoisier's). We have already [illegible] with this spirit (which is guaranteed to be genuine [illegible] in the Analytical Records of THE LANCET. What [illegible] described as a liqueur known as "satinette" is [illegible]ade by this firm. It resembles gin but has a [illegible] flavour and is more mellow. Messrs. George Back [illegible] Co. (13, Devonshire-square, London, E.C.) showed specimens of their diabetes whisky, so called because it is free from excess of acidity, extractives, or saccharine matters.

Publications were well represented. Of a special kind were the medical books, anatomical diagrams, clinical figures, and charts of Messrs. John Bale, Sons, and Danielsson (83, 85, 87, 89, Great Tichfield-street, Oxford-street, London, W.). Messrs. Wodderspoon and Co. (7, Serle-street, Lincoln's Inn, London, W.C.) exhibited a variety of charts—temperature, diet, and four-hour and two-hour charts. Publishers and booksellers were represented at various stalls by the following: Messrs. Rebman, Limited (129, Shaftesbury-avenue, Cambridge-circus, London, W.C.), Messrs. W. B. Saunders and Co. (161, Strand, London, W.C., and Philadelphia), Mr. Henry Kimpton (13, Furnival-street, Holborn, London, E.C.), the Scientific Press, Limited (28 and 29, Southampton-street, Strand, London, W.C.), and the *Medical Times* publications, &c.

We understand that the attendance of visitors at the exhibition this year was not less satisfactory than on previous occasions, amongst those present during the week being a large number of medical men and of the staff of nursing institutions and hospitals.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTION OF MEMBERS OF COUNCIL.

ON Thursday, July 4th, a meeting of the Fellows will be held for the election of three members of Council who retire by rotation. As Sir William Mac Cormac, Bart., K.C.B., K.C.V.O., will be President on the day of election he will retain his seat on the Council for another year.

The following list of the 24 members of the Council gives the date at which each member will retire:—

Retire in 1908: Mr. Alfred Cooper (first elected 1892); Dr. J. Ward Cousins, Royal Portsmouth Hospital (first elected 1895); and Mr. A. Pearce Gould, Middlesex Hospital.

Retire in 1907: Mr. T. R. Jessop, Leeds General Infirmary (first elected 1891); and Mr. H. W. Page, St. Mary's Hospital.

Retire in 1906: Mr. F. Richardson Cross, Bristol Royal Infirmary; Mr. Henry Morris, Junior Vice-President, Middlesex Hospital (first elected 1893); and Mr. John Langton, Senior Vice-President, St. Bartholomew's Hospital (first elected 1890).

Retire in 1905: Mr. H. G. Howse, Guy's Hospital (first elected 1889); Mr. Edmund Owen, St. Mary's Hospital; and Mr. Rickman J. Godlee, University College Hospital.

Retire in 1904: Mr Thomas Bryant, Guy's Hospital (first elected 1880); Mr. T. Pickering Pick, St. George's Hospital (first elected 1888); and Mr. J. Tweedy, University College Hospital (first elected 1892).

Retire in 1903: Mr. A. Willett, St. Bartholomew's Hospital (first elected 1887); Mr. H. T. Butlin, St. Bartholomew's Hospital; and Sir F. Treves, London Hospital.

Retire in 1902: Sir William Mac Cormac, President, St. Thomas's Hospital (first elected 1883); Mr. Reginald Harrison (first elected 1886); Mr. Howard Marsh, St. Bartholomew's Hospital (first elected 1892); and Mr. J. Hardie, Royal Infirmary, Manchester.

Retire in 1901: Mr. N. C. Macnamara, Westminster Hospital (first elected 1885); Mr. A. W. Mayo Robson, Leeds General Infirmary; and Mr. W. Watson Cheyne, King's College Hospital.

Of the three members whose term of office expires this year we believe that only Mr. Mayo Robson and Mr. Watson Cheyne have decided to apply for re-election. Several other Fellows, we understand, are coming forward. Among them are Mr. H. H. Clutton of St. Thomas's Hospital, Mr. Jordan Lloyd of Birmingham, Mr. Clement Lucas of Guy's Hospital, Mr. J. H. Morgan of Charing Cross Hospital, Mr. C. Mansell Moullin of London Hospital, and Mr. Bland-Sutton of Middlesex Hospital. The nomination papers have to reach the College by Monday next, June 10th. At present St. Bartholomew's Hospital has four representatives, Guy's Hospital, St. Mary's Hospital, Middlesex Hospital, and University College Hospital have two representatives each, and the following hospitals have one representative apiece: St. George's, King's, London, St. Thomas's, and Westminster. Two members of the Council are attached to special London hospitals and five are attached to provincial hospitals; Leeds General Infirmary has two representatives, and the Bristol Royal Infirmary, the Manchester Royal Infirmary, and the Royal Portsmouth Hospital have each one.

ANNUAL MEETING OF FELLOWS.

The annual meeting of the Fellows of the College will be held on Thursday, July 4th, at 5.30 P.M., for the consideration of any motions which may be introduced by Fellows. Any motion which it is desired should be brought before the meeting must be signed by the mover and must be received by the secretary not later than June 13th. As no quorum has been present on the last four occasions for which a meeting of Fellows has been called it is to be hoped that such a fate will not befall the coming meeting, and we would urge all Fellows to be present who have at heart the continuance of these meetings. It is desirable also that suitable subjects for discussion should be provided.

It will be remembered that in future the annual report of the Council will be sent to those Fellows and Members only who have specially asked for it. To save the trouble of annual application a list is to be kept of Fellows and Members who desire to receive the report regularly. A form for this purpose has been sent to the Fellows, and it must be filled up and returned if the report is desired.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

AT the annual meeting of the Fellows held on June 1st a most satisfactory report was presented. The College is entirely free from debt and has increased its investments within the year by the purchase of £3000 stock of the Midland Great Western Railway of Ireland. During the past 12 months many of the Fellows and Licentiates received honours and distinctions for services in the South African campaign. One received the Knight Commandership of the Bath, five the Companionship of the Bath, one the Knight Commandership of St. Michael and St. George, two the Companionship of St. Michael and St. George, and five the Distinguished Service Order, and 13 commissions in the Royal Army Medical Corps were granted without further examination to Licentiates of the College—some of these were the reward for services in the field in the present war. The Arnott medal, intended by the donor to be awarded to the member of the profession—civil, naval, or military—who during the previous three years had the most heroic and distinguished record, was conferred on a Licentiate of the College. There are at present living 10 honorary Fellows, 418 ordinary Fellows, 2791 Licentiates, 9 honorary Diplomates in Public Health, 102 ordinary Diplomates in Public Health, and 496 Licentiates in Dental Surgery.

A meeting was also held on June 3rd to elect the officers for the ensuing year. The following were elected:—President: Mr. Thomas Myles. Vice President: Mr. L. H. Ormsby. Honorary secretary: Sir Charles A. Cameron, C.B. Council: Sir Philip C. Smyly, Mr. H. R. Swanzy, Mr. E. H. Bennett, Mr. W. Stoker, Sir Charles A. Cameron, C.B., Mr. Austin Meldon, D.L., Mr. C. B. Ball, Sir William Thomson, C.B., Mr. J. B. Story, Mr. J. Lentaigne, Mr. Arthur Chance, Mr. R. D. Purefoy, Mr. H. G. Sherlock, Mr. R. Bolton McCausland, Mr. F. Conway Dwyer, Mr. J. S. McArdle, Mr. R. H. Woods, Mr. R. Lane Joynt, and Mr. P. W. Maxwell.

THE SOUTH AFRICAN CIVIL SURGEONS' DINNER.

ON the evening of June 5th Sir WILLIAM MACCORMAC, Bart., K.C.B., K.C.V.O., presided at a large gathering of civilian medical men who, having returned from service in the war in South Africa, dined together at the Hotel Cecil.

The CHAIRMAN, in proposing the loyal toasts, which were enthusiastically received, referred to the active interest which Queen Alexandra had taken with regard to the care of the sick and wounded.

Sir FREDERICK TREVES, K.C.V.O., proposed "The Navy, Army, and Reserve Forces," which was replied to by Rear-Admiral Sir ROBERT H. HARRIS, K.C.B., and the Secretary of State for War.

Mr. BRODRICK apologised for the unavoidable absence of Lord Roberts and said that the Commander-in-Chief had charged him to express to those present his lordship's high appreciation of the admirable services of the civil surgeons in South Africa. The medical authorities had furnished the Government with some 700 recruits in a time of emergency and he thought that there should be a good understanding between the military authorities and those high authorities who had furnished the recruits. There had been a great deal of criticism on the medical arrangements of the war, but those persons who criticised generally overstated their case. Even if there were points on which amendment was desirable the universal condemnation expressed by some persons of the zeal, ability, and organisation with which they had to deal had overshot its mark and had caused some revulsion of feeling in favour of those who, under great difficulties, had tried to accomplish the task which they had had to fulfil in South Africa. Undoubtedly they recognised that with greater demands and the stress of modern appliances some changes were necessary and that now was the proper moment to apply those changes. Although he desired nothing more ardently in respect of the Medical Department than to obtain the best civilian guidance in perfecting their arrangements, and although he hoped to ask very shortly some of those who could most help them in that respect from among the higher authorities of the civilian profession to advise them on those changes which, whether in regard to elasticity of terms or improvement of position, might enable them to get the best candidates for the medical service, still he could not help feeling that they had an organisation on which might be founded not merely something which was effective but something which, as their experience was most recent, entitled them to obtain a medical organisation for the army which would place them in the fore-front of all European peoples. But while the Government would willingly avail themselves of the experience of those who had come to their rescue in South Africa, he trusted that the patriotism of the medical profession would also assist them in perfecting a scheme which would give to the country the best medical organisation in the world. Mr. Brodrick concluded his speech by reviewing the recent events in South Africa and expressed the determination of the Government to do everything that was possible to induce the country to continue that patient endurance which was necessary at this stage of the war, and which alone could bring these operations to a satisfactory issue and guarantee for us an honourable and a lasting peace.

Mr. G. H. MAKINS, C.B., proposed "The Army in South Africa," to which Major-General IAN HAMILTON, K.C.B., responded, and in doing so paid a high tribute to the services which the medical profession had rendered to the army in South Africa. Referring to a case in connexion with his own command he said that every civil surgeon or member of the Royal Army Medical Corps had done the work of about 10 men, working night and day. He referred specially to the services of Colonel W. D. C. Williams C.B., of the New South Wales Army Medical Corps, and of Dr. Fremantle.

Mr. A. D. FRIPP, C.B., C.V.O., proposed the toast of "The Royal Army Medical Corps," which was responded to by Surgeon-General J. JAMESON, C.B., who expressed his gratitude for the very excellent services rendered by the civil surgeons in South Africa, many of whom, out of a spirit of loyalty and patriotism, had given up good practices and hospital appointments, severed family ties, renounced home comforts, and braved the risks which belonged to war. He said that he had been able to supply every demand from South Africa both of *personnel* and material, and those present that night were the best judges of its efficiency. There were some 700 civil surgeons employed and in selecting them he was greatly indebted for the help which he had received from deans and teachers of metropolitan schools and from professors of universities. He took the present opportunity of thanking Professor D. J. Cunningham of Dublin and Professor McCall Anderson of Glasgow. Three civil surgeons were killed in action and nine died from disease. Four of the 523 men of the Royal Army Medical Corps were killed in action, two died from wounds, and 12 from disease. Enteric fever was responsible for the large majority of sickness; this disease furnished 85 cases. Dysentery gave 39 cases and simple continued fever 21 cases. From enteric fever the rank and file suffered in about the same proportion as did the medical officers.

The toast of "The Guests" was proposed by Mr. A. A. BOWLBY, C.M.G., and replied to by Sir ROBERT ROMER, G.C.B. and Major General EATON. "In memoriam" was proposed by Sir W. THOMSON, C.B., and "The Chairman" by Mr. CLINTON DENT.

ASYLUM REPORTS.

City and County of Bristol Asylum (Annual Report for 1900).—The average number of patients resident during the year was 784 and comprised 368 males and 416 females. The admissions during the year amounted to 246 and of these 161 were females and 85 were males. Of these, 29—viz., 7 males and 22 females—were not first admissions. Dr. Harry A. Benham, the medical superintendent, states in his report that 40 female patients boarded out temporarily at the Gloucester County Asylum were received here in July, 1900, and all patients chargeable to the city of Bristol are now under treatment in the asylum. There are 19 male boarders from unions under the control of the London County Council and 3 from other unions in the county. Dr. Benham is of opinion that in the city of Bristol "no great increase (of insanity) has been experienced in the last few years." Reconstruction and enlargement of the whole of the administrative and residential block of the institution were necessitated in 1889, and the building was pulled down and rebuilt. It was opened in 1892 and was furnished with accommodation sufficient to provide for over 1000 patients. In 1897 fresh buildings to provide for 150 more female patients and an isolation hospital were commenced. These have just been completed. Permission has been obtained to provide additional buildings for 59 male patients. Owing to the foresight displayed in securing the necessary land and the erection of suitable buildings there will probably arise no need for further extension for several years, and this period "may be largely extended if the Poor-law guardians carry out the contemplated provision for chronic cases capable of treatment in the imbecile wards of a workhouse. The removal of this class of patients from the asylum," says Dr. Benham, "is what I have earnestly advocated for many years. . . . It will give this institution an opportunity of doing further justice to those cases capable of improvement which should be the primary object of asylum treatment, and which is hindered by the presence of those helpless and incurable cases whose retention is found to be detrimental to the recovery of those amenable to treatment." The number of cases discharged as recovered during the year amounted to 97—viz., 39 males and 58 females, or 12 37 per cent. of the average number resident. The deaths during the year amounted to 94—viz., 44 males and 50 females, or 12 per cent. as calculated on the same basis. Of the deaths, one was due to colitis, two were due to cancer, three to epilepsy, *four* to bronchitis, six to senile decay, nine to cardiac disease, 11 to pneumonia, 11 to renal disease, 11 to general paralysis, 13 to œdema of the lungs, and 13 to phthisis and tuberculosis. "33 deaths, or more than one-third of the whole number, occurred in the March quarter when influenza was epidemic in the asylum." There has not been a single coroner's inquest during the year. In 87 cases of deaths post-mortem examinations were made. The electric installation is at last almost completed and the whole of the main buildings are now lighted by electricity. The new land acquired by exchange from the Bristol guardians is now under cultivation and the amount of garden ground capable of being worked by the patients is more than doubled. This enables suitable employment to be found for inmates and the produce of vegetables is increased. The Lunacy Commissioners state in their report that the day-rooms and dormitories were in excellent order and that comfort and the utmost cleanliness prevailed. There was no employment of mechanical restraint or seclusion during the year. The condition of the case-books and other medical records and the prosecution of much original pathological research showed that both diligence and efficiency prevailed in the medical staff.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 5321 births and 3580 deaths were registered during the week ending June 1st. The annual rate of mortality in these towns, which had been 16·8 and 16 7 per 1000 in the two preceding weeks, further declined last week to 16·3 per 1000. In London the death-rate was 15 4 per 1000, while it averaged 16·8 in the 32 large provincial towns. The lowest death-rates in these towns were 9 3 in Brighton, 10·8 in Croydon, 11·6 in Norwich, and 11 9 in Halifax; the highest rates were 19·8 in Sunderland, 20 9 in Oldham, 22 5 in Hull, and 22 6 in Preston. The 3580 deaths in these towns last week included 360 which were referred to the principal zymotic diseases, against 371 and 386 in the two preceding weeks; of these, 118 resulted from measles, 83 from whooping-cough, 46 from scarlet fever, 44 from diphtheria, 40 from diarrhœal diseases, and 29 from "fever" (principally enteric). No death from any of these diseases was registered last week in Huddersfield; in the other towns they caused the lowest death-rates in Croydon, Plymouth, and Norwich, and the highest rates in Swansea, Bolton, Preston, and Gateshead. The greatest mortality from *measles occurred in Birmingham, Wolverhampton, Liverpool,* Bolton, and Gateshead; from scarlet fever in Oldham and Preston; from whooping-cough in Swansea, Preston, and Sunderland; and from "fever" in West Ham and Swansea. The mortality from diarrhœal diseases showed no marked excess in any of the large towns. The 44 deaths from diphtheria included 13 in London, four in Cardiff, four in Birmingham, three in West Ham, three in Leicester, three in Liverpool, and three in Blackburn. No fatal case of small-pox was registered last week in any of the 33 large towns; and only one small-pox patient was admitted into the Metropolitan Asylums hospitals during the week and remained under treatment on Saturday, June 1st. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2352, against numbers increasing from 1522 to 2241 on the five preceding Saturdays; 318 new cases were admitted during the week, against 397, 323, and 341 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in *London, which had been 249* and 191 in the two preceding weeks, rose again last week to 240, but were 38 below the corrected average. The causes of 41, or 1·1 per cent., of the deaths in the 33 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Nottingham, Salford, Newcastle, and in 10 other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Halifax, Hull, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·2, 20·3, and 20·7 per 1000 in the three preceding weeks, declined again to 20·1 during the week ending June 1st, but showed an excess of 3 8 per 1000 over the mean rate during the same period in the 33 large English towns. The death-rates in these Scotch towns ranged from 12 9 in Leith and 17·4 in Perth to 25·3 in Greenock and 26 7 in Paisley. The 638 deaths in these towns included 47 which were referred to whooping-cough, 24 to diarrhœa, 17 to measles, four to diphtheria, three to "fever," one to small-pox, and one to scarlet fever. In all, 97 deaths resulted from these principal zymotic diseases last week, against 89 and 94 in the two preceding weeks. These 97 deaths were equal to an annual rate of 3·1 per 1000, which was 1·5 above the zymotic death-rate last week in the 33 large English towns. The fatal cases of whooping-cough, which had been 49, 41, and 40 in the three preceding weeks, rose again last week to 47, of which 22 occurred in Glasgow, 17 in Edinburgh, four in Paisley, and two in Dundee. The deaths from diarrhœa, which had been 18 and 30 in the two preceding weeks, declined again to 24 last week, and included 16 in Glasgow, four in Edinburgh, and two in Dundee. The fatal cases of measles, which had been 15 and 19 in the two preceding weeks, decreased again last week to 17, of which 12 were registered in Glasgow, two in Edinburgh, and two in Greenock. The three deaths from "fever" were all recorded in Glasgow, where two of the four fatal cases of diphtheria and the death from small-pox also occurred. The deaths referred to diseases of the respiratory organs in these towns, which had been 101 in each of the two preceding weeks, rose last week to 107, and slightly exceeded the number in the corresponding period of last year. The causes of 26, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 27·4, 27 4, and 26 5 per 1000 in the three preceding weeks, further declined to 23 0 during the week ending June 1st. During the past four weeks the death-rate in the city has averaged 26 1 per 1000, the rates during the same period being 15 7 in London and 21·3 in Edinburgh. The 153 deaths of persons belonging to Dublin registered during the week under notice were 22 below the number in the preceding week, and included five which were referred to the principal zymotic diseases, against 15, 10, and nine in the three preceding weeks; of these, two resulted from whooping-cough, two from "fever," and one from diphtheria These five deaths were equal to an annual rate of 0·8 per 1000, the zymotic death-rates during the same, period being 1·6 in London and 3 9 in Edinburgh. The fatal cases of whooping-cough, which had been nine, seven, eight, and five in the four preceding weeks, *showed* a further considerable decline last week. The 153 deaths in Dublin last week included 22 of children under one year of age and 38 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons were fewer than in the preceding week. Four inquest cases and three deaths from violence were registered, and 74, or nearly one-half, of the deaths occurred in public institutions. The causes of five, or more than 3 per cent., of the deaths in the city last week were not certified.

IRISH VITAL STATISTICS.

WE have been favoured by the Registrar-General of Ireland with a copy of his summary of births and deaths registered in the quarter ended in March last. In a courteous letter Mr. Matheson draws our special attention to certain important matters dealt with in this summary for the first time. As a prominent feature in the pamphlet, we notice a new table, showing for the city of *Dublin and* the urban districts of Rathmines and Pembroke the number of deaths which occurred among children whose lives had been insured. Of the children under 10 years of age who died during the quarter as many as 46 per cent. were insured. The Friendly Societies Act limits the amount which may be paid at death to £6 in the case of a child under five years and to £10 in the case of a child under 10 years. The table indicates that it is among very young children mainly that insurances are effected in Dublin, nearly three-fourths of the insured children being under three years of age at the time of their death. Mr. Matheson, however, gives no reason for suspecting that foul play has been generally resorted to in connexion with life insurance; on the contrary, he shows that out of 397 insured children dying last quarter as many as 378 were registered on the evidence of a medical certificate of cause of death.

The burial of stillborn children is the next point referred to in the summary before us. From returns which were furnished to the Registrar-General it appears that the interments of 83 stillborn children were reported at one or other of the cemeteries in Dublin—a number equal to 3·1 per cent. of the total births. Under existing law neither the births nor the deaths of stillborn infants are registrable—a fact which in the opinion of those best qualified to judge opens wide the door for the commission of crime. The Select Committee of the House of Commons whose valuable report on death-certification was published in 1894 drew attention to this defect in the law and recommended that legislation should be sought to compel the registration of stillbirths and to prohibit the burial of stillborn children without suitable precautions. Meantime the Irish Registrar-General is to be commended for bringing into due prominence this important subject and also that of the burial of infants who lives have been insured.

The third point to which Mr. Matheson invites attention is the occurrence in Dublin of an epidemic of "cerebro-spinal meningitis" during the last 18 months. Within that period as many as 77 deaths have been caused by this disease in the Dublin registration area alone, or more than double the number that occurred during the same time in the whole of England and Wales. Two tables are given in the summary, the one giving the localities invaded by the disease within the Dublin area, the other showing the occupations and the age at death of the 77 persons who fell victims to the recent epidemic which now happily appears to be on the wane.

We are glad to observe that the useful table (a special feature of the Dublin report) which gives the occupation or social position of those dying from time to time is still continued. It is greatly to be desired that the authorities at Somerset House may see their way to inaugurate similar returns for England and Wales. Based on a population exceeding 32 millions such statistics would be of high scientific value and interest.

We complete our notice of this interesting summary with a suggestion which, we hope, will be accepted in the spirit in which it is offered—namely, that a column should be added to Table IV., showing the *ratio of infantile mortality under one year to 1000 births*. The necessary facts are already given, but the additional column suggested would greatly add to the value of the table, for infant mortality is now regarded as the truest test of what is implied in the term "sanitary condition."

THE SERVICES.

ARMY MEDICAL SERVICE.

SURGEON-GENERAL J. JAMESON, C.B., Honorary Surgeon to the King, Director-General of the Army Medical Service, is placed on retired pay.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Alfred Goodwyn Kay, is seconded for service on the Staff. Civil Surgeon Daniel Litton Harding to be Surgeon-Lieutenant.

Lieutenant Davidson has left Aldershot for duty in the North-Western District. Lieutenant Parsons has been ordered to hold himself in readiness to embark for Malta at an early date. Lieutenant T. F. White, doing duty at the 3rd Station Hospital, Aldershot, holds himself in readiness to embark for the Cape at an early date. Major S. O. Stuart has joined at Woolwich. Colonel W. E. Saunders, C.B., has embarked for India. Major A. R. Aldridge is appointed Sanitary Officer, Bengal Command, vice Major L. P. Mumby.

IMPERIAL YEOMANRY.

Duke of Lancaster's Own: Surgeon-Major W. W. Wingate-Saul to be Surgeon-Lieutenant-Colonel.

VOLUNTEER CORPS.

Rifle: 2nd Volunteer Battalion the Lancashire Fusiliers: Surgeon-Captain W. Pooley to be Surgeon-Major. 3rd (Dumfries) Volunteer Battalion the King's Own
Scottish Bo
his commiss
Lieutenant.
Regiment:
graph 118
and St. Ge
be Surgeon-
tenant C. A.

VOLUNTEER MEDICAL STAFF CORPS.

The Glasgow Companies: Surgeon-Lieutenant R. T. Halliday, from the 5th Volunteer Battalion Princess Louise's (Argyll and Sutherland Highlanders), to be Surgeon-Lieutenant. The Manchester Companies: Surgeon-Lieutenant W. B. Pritchard to be Surgeon-Captain.

ROYAL MILITARY TOURNAMENT.

The Royal Military Tournament, if not quite up to the standard of some other years, is nevertheless a splendid spectacle, but for some reason it has not awakened the enthusiasm of the general public which usually characterises this annual entertainment at the Agricultural Hall, Islington. The war in South Africa may have something to do with this apathy or it may be that the disposal of the surplus of last year's receipts did not meet with general public approval. But whatever the cause, the comparatively small attendances are to be regretted, for apart from the fact that the tournament affords pleasant recreation to thousands, the great tournament of the year and with it the local tournaments do not a little to improve the physique of the army and act also as a stimulus to recruiting. In addition to the usual fencing, riding, and other competitions which take place during the fortnight for which the tournament remains open there are one or two items in the programme to which we may call special attention. One of these is the display by the Royal Marine Artillery in which a naval 5-inch gun after being drawn into the arena together with portable shears is taken from its carriage, mounted, fired, dismounted, and again made ready for removal in a little over five minutes. It is an exciting performance and one which is watched with the keenest interest by both the seeker after amusement and the lover of practical utility. Then there is the display by a detachment from H.M.S. *Excellent* and the smart manner in which the men handle the guns brings forth deafening rounds of applause. The musical drive by the Royal Horse Artillery and the musical ride by the 1st Life Guards are also items on the programme well worth seeing, and the clever and graceful bareback riding by men from the cavalry depôt at Canterbury always meets with approval. The "set piece," if we may use the term, of the tournament is always the pageant which this year illustrates the inauguration of the Australian Commonwealth, and every corps that participated in that ceremony is represented. The scene is a pretty one and is also well worth seeing from an educational point of view. The final display represents an attack upon, and defence of, an Indian village the occupants of which are attacked while holding a gymkhana. A feature of this performance is the building of a bridge by the Royal Engineers which is held against a supposed enemy by two Royal Horse Artillery guns. It is to be hoped that no serious accident will happen in connexion with this last item, but the pontoon wagons have to be manœuvred in a very confined space and the horses drawing the wagons sometimes become frightened by reason of the noise and antics of the performers in the gymkhana.

The medical and sanitary arrangements are under the supervision of the principal medical officer, Major G. H. Barefoot, R.A.M.C., who is assisted by Lieutenant H. J. McGrigor, R.A.M.C. We have always maintained that the Agricultural Hall was never intended for the housing of a large number of troops and horses and at the same time to accommodate a large number of spectators, but the medical officers who have been responsible for adapting the building to the purposes of the Royal Military Tournament have year by year caused improvements to be made in the matter of sanitation and ventilation until at the present time the building is as perfectly adapted to the purposes of the tournament as it is possible to make it. Some 1000 men sleep in the buildings in cubicles and there are 12 baths fitted with hot and cold water allotted to their use. The food, which is of excellent quality, is cooked in the building and served to the men in parties of 200 at a time, the mess-room being cleared up after each party of 200 have had their meal. The arrangements made for accidents are also praiseworthy. At each end of the arena an orderly is stationed with a medical haversack and water-bottle, while a stretcher party is always in attendance at one side of the arena at a point immediately below the Royal box. An ambulance wagon with two horses constantly harnessed is also kept in readiness for emergencies. Within a few yards of the principal entrance a small hospital has been fitted up for slight injuries, more serious cases being sent to the Guards' Hospital at Rochester-row. In the case of very serious accidents arrangements have been made to send the patients to the nearest civil hospital. The tournament will close on June 13th.

SOUTH AFRICAN WAR NOTES

Major-General H. F. Eaton has issued an appeal on behalf of the Soldiers' and Sailors' Help Society for discarded clothes for returned soldiers. He points out that the great difficulty in obtaining a situation is due to the discharged soldier's want of decent civilian clothing. A branch of the society is being started for the purpose of collecting clothing, and the committee would be much obliged if any gentlemen having clothing, including shirts and underwear, for which they have no further use, would kindly give it for the use of the men. To save the donors any unnecessary trouble or expense in the matter arrangements have been made with Messrs. Carter, Paterson, and Co., to collect parcels within their area at reduced rates if those giving clothes will kindly send a post-card addressed to the firm at 128, Goswell-road, E.C., requesting them to collect any parcels they may wish to send. Articles of clothing will also be received at the following addresses . Captain Simpson, 70, Victoria-street, S.W.; the Employment Branch of the Soldiers' and Sailors' Help Society, 115, Ebury-street; the offices of the Soldiers' and Sailors' Help Society, 17, King-street, St. James's, S.W.; Captain S. Waters, 28, Overton-road, Brixton, S.W.; and Mr. Oliver Williams, 71 and 72, King William-street, E C.

Surgeon-Lieutenant Colonel Kilkelly, C B , principal medical officer of the Imperial Yeomanry Hospitals, states that there remained in the hospital on May 8th 31 officers and 367 non-commissioned officers and men. The total admissions at that date were 3993 in-patients and 911 out-patients. Dr. Richmond of Guy's Hospital sailed on June 4th in the *Britannic* to take up his duties as principal medical officer of the new branch opened by the Imperial Yeomanry Hospitals Committee at Elandsfontein.

The following have been discharged from hospital to duty:—Lieutenant P. S. Lelean, R.A.M.C., and Major J. B. Buchanan, R.A.M.C., Civil Surgeons John Harry Saunders, John Law Aymard, William Hutton Nicol, Ralph John Jupp, Frank Lindsley Dickson, Herbert Hollick, Clement John Baker, and Leonard Bowring Betts.

Civil Surgeon Wilbond is still reported seriously ill (May 31st). Lieutenant Stock, R A.M.C., is reported much improved.

Major H. J. Wyatt, R.A.M.C , and Major A. Wright, R.A.M.C., are on passage home.

AFFAIRS IN SOUTH AFRICA.

At the moment of our writing the daily journals are full of exciting, but not very satisfactory, intelligence of a military character from South Africa and of a political nature in regard to that country and the war. We have nothing, of course, to do with the latter, but we may nevertheless remark that it is calculated to raise the "eyebrows of astonishment," as the Germans say, to notice how completely some facts connected with the past history of the war seem to have been altogether ignored by some writers at the present time. That the South African republics had been for years making their preparations, that the declaration of war came from them and not from the British Government and was immediately followed by an invasion on their part of British territory are, we take it, facts which cannot be denied. But to read some of the statements which are now published it would be thought that the Government of this country was the sole aggressor, had begun the war, and had from first to last pursued a cruel and tyrannically aggressive policy in regard to a simple pastoral people fighting in defence of their homes, their rights, and for a reasonable amount of independence. Now that they have slain large numbers of our troops and caused an enormous outlay of treasure it is our duty to make peace on their terms and to incur the risk of having to go through the whole thing again at some future date. The details of the Vlakfontein fight show what an uncommonly severe fight it was, and it is comparatively easy to understand how it was brought about. It was of the nature of an ambuscade. The enemy rushed the rearguard under cover of the smoke of a veldt fire; and as regards the 100 men of the Derbyshire Regiment, as they lost over 80 of their number it is clear that they were surprised and shot down almost at once. The force in advance of its rearguard soon took part in the fight and succeeded in recapturing some guns and driving off the attacking Boer force. The Boers left 41 dead on the field, but their further casualties are not known; whereas ours are—and they are heavy—six officers and 51 men killed, six officers and 115 men wounded, and one officer and seven men missing. An officer and four men have since died from their wounds. In Cape Colony Jamestown was looted of its stores by the Boers, but the enemy were followed up and most of the stores were recovered.

In addition to the casualty list attributable to these occurrences there are many deaths and a good deal of sickness from disease causes, notably from enteric fever.

HONOURS FOR FRENCH NAVAL MEDICAL OFFICERS

The Conseil Supérieur de Santé has decided to award the Prix de Médecine Navale for 1900 to Dr. H. J. A. Reboul, principal medical officer of the Cochin China Naval Division, the annual inspection report sent in by that officer having been adjudged to be the best of all that were submitted The Conseil also mentions with commendation no fewer than six other reports by medical officers of the higher ranks and takes the opportunity of drawing the attention of the Minister of Marine to them in order that the authors may receive official recognition for their labours. Five of the officers in question were in medical charge of first-class ironclads, the sixth being principal medical officer of the Pyrotechnic School at Toulon.

THE LEGION OF HONOUR.

In virtue of a Ministerial decision dated Feb. 28th, 1901, the name of Dr. Conan, first class medical officer in the French navy, has been noted for promotion to the rank of Chevalier of the Legion of Honour in recognition of his gallantry and devotion while in medical charge of the Malagasy tirailleurs during the late campaign in Madagascar.

THE VICTORIA CROSS.

The King has signified his intention to confer the decoration of the Victoria Cross on Captain N. R Howse F.R.C.S. Eng., L R.C P. Lond., of the New South Wales Medical Staff Corps, for the following act of courage — "During the action at Vredefort on July 24th, 1900, Captain Howse went out under a heavy cross fire and picked up a wounded man and carried him to a place of shelter."

DEATHS IN THE SERVICES.

Surgeon - Captain Francis Welford, M.B., of the 7th Battalion Imperial Yeomanry, who died from wounds at the engagement at Vlakfontein on May 29th, went out to South Africa last year and was gazetted as temporary Captain on Feb. 24th, 1900.

Major W. A. Morris, R.A.M.C., the honorary secretary of the Ambulance Section of the Naval and Military Exhibition at the Crystal Palace, asks us to inform medical men and others who have written any books on ambulance work or who have invented any ambulance material, that the Ambulance Committee of the exhibition is very anxious to have as complete a collection as possible, and they would be glad to receive such articles. The Crystal Palace Company will pay all expenses and Major Morris will be very happy to afford to anyone who may be inclined to contribute to the success of the ambulance exhibition every assistance if they will write to him at the Crystal Palace

---

BRISTOL LUNATIC ASYLUM.—The fortieth annual report of the Visiting Committee of the *Bristol Lunatic Asylum, Fishponds*, shows that at the end of 1900 there were 814 patients (369 males, 445 females) in the institution, against 799 (383 males, 416 females) on Dec. 31st, 1699 The extension on the female side has been completed during the past year and three of the four new wards are occupied by patients. The new dining-hall has been opened and the isolation hospital has now been completed. During 1900 the percentage proportion of recoveries to admission was 50 and the percentage proportion of deaths to the average number resident was 11 99.

"Audi alteram partem."

"ARTERIAL HYPERTONUS AND ARTERIO SCLEROSIS"

To the Editors of THE LANCET

SIRS,—In his valuable paper on Arterial Hypertonus and Arterio Sclerosis, in THE LANCET of June 1st, p 1519, Dr W Russell points out that while in arterial hypertonus the middle coat of the arteries in general is thickened, that of the intra renal arteries, far from being thickened, may be actually atrophied This observation is of peculiar interest to me, confirming as it does a view which suggested itself to me some years ago—in my student days, in fact My Michael Foster had taught me that the most efficacious way of increasing the urinary flow vaso-motorially is by a dilatation of the arteries of the renal area and a constriction of the remaining systemic arteries, the effect of this latter being to send up the blood pressure in the aorta and so to force the blood in increased abundance and under increased pressure through the dilated renal area These physiological facts I sought to apply to the pathology of granular kidney In this disease there are general systemic arterial constriction, toxæmia, and polyuria, and I argued that the polyuria is for the purpose of relieving the toxæmia and that it is induced vaso-motorially in the manner just described Now, if this explanation be correct, the media should be thickened in all the systemic arteries save those of the renal area which should not show thickening of this coat At that time, however, all the evidence seemed to be in favour of these latter vessels being affected in the same way as the other systemic arteries, and thus, while I have never been able wholly to dissuade myself that the arterial hypertonus met with in granular kidney and allied toxæmic states is for the purpose of aiding the elimination of the toxins I could not completely satisfy myself that such was actually the case Dr Russell's observation, however, appears to remove the only difficulty in the acceptance of this view

One word as to the thickening of the intima in arterial hypertonus Dr Russell attributes it to the direct action of the poisonous blood It seems difficult to believe that a poison freely circulating throughout the body picks out and irritates the intima throughout the entire systemic arterial tree while leaving the other connective tissues unaffected Such a view implies that the connective tissues have the same kind of selective power for toxins as have nerve tissues I suggest the following explanation of the thickening in question 1 There is toxæmia 2 In consequence of this all the arteries, save the intra renal, contract 3 As a result of this increased peripheral resistance the blood pressure in the entire systemic arterial tree rises This would happen even though the heart did not beat more powerfully, but it does beat more powerfully in order to maintain the normal flow into the veins, and thus the blood pressure is still further augmented 4 This increased pressure increases the tension in the media and the intima The strain must, of course, be felt by the media, since this coat by its active contraction has to exert a pressure equal to the blood pressure, otherwise it would be merely yielding passively It must also be felt by the intima which is compressed by the actively contracting media on the one hand and the blood on the other The strain will, however, not be felt by the adventitia, for when the media contracts it drags the adventitia with it, thus actually diminishing the tension in the latter 5 The intima being subjected to this strain, week in week out, year after year, thickens, while the unstrained adventitia suffers little or no change

If the above explanation be correct I should expect to find the adventitia of the intra renal arteries greatly thickened, seeing that it is apparently not protected from strain by an actively contracting media

I am, Sirs, yours faithfully,

Wimpole-street, W, June 3rd, 1901 HARRY CAMPBELL

"LOCAL *v* GENERAL ANÆSTHESIA IN CERTAIN CASES OF ABDOMINAL SURGERY."

To the Editors of THE LANCET.

SIRS,—In spite of the strictures of Dr S H Long[1] and Dr J Blumfeld,[2] I think that Mr T H Morse[3] has done well to draw attention to a subject which as yet has not received sufficient attention at the hands of the profession and is, in fact, practically in its infancy.

Possibly, if every medical man called upon to assist a surgeon in the performance of a critical and urgent operation were as able an anæsthetist as is Dr Long or Dr. Blumfeld, the subject of local anæsthesia might not be worth further consideration These gentlemen naturally consider the subject mainly from their own special point of view, and yet it is not difficult to conceive an urgent case in which, through some cardiac or pulmonary affection, both Dr Long and Dr Blumfeld would think twice before putting the patient under a general anæsthetic, would only administer such with extreme care, and would be glad when the operation was safely over If that applies to them how much more does it apply to the rank and file of the profession, who, in many cases, are entirely unskilled in the use of anæsthetics and whose administration of them in a critical case would probably cause a "shock" to the operator if not to the patient In this direction Mr Morse must have a varied and not always an enviable experience Called at a moment's notice to operate all over the county he must rely on the assistance of the medical man in charge, often in an isolated district, miles away from any further help What a boon in such a case to be able to dispense with a general anæsthetic and to utilise the services of his *confrère* in the performance of the operation! What a blessing to run no risk from the vomiting and malaise so frequently following the administration of a general anæsthetic! How portable, also, a little eucaine and a hypodermic syringe are! No risk of bursting or leaking bottles, no anxiety—as I have had—as to whether the chloroform or ether will hold out Both Mr Morse's critics allude—as he does—to the risk under general anæsthesia of the patient inhaling some vomit, and point out the means to prevent such a disaster This is all very well with a hospital with everything handy, or with a skilled anæsthetist who, I presume, has always got the necessary tube, &c, in his bag, but what about an urgent case in the country—would not a subcutaneous injection of eucaine be preferable with none of this risk?

Again, has a really safe general anæsthetic been discovered? Have not deaths occurred from them all? Ether, I believe, has not an absolutely clean sheet in this respect I am quite aware that Mr Morse is only one pioneer in this direction, but his efforts deserve encouragement rather than the strictures they have met with at the hands of his critics, who mainly discuss his opening statements on the causation of shock after operations and seem not much to look beyond, but, shock or no shock local anæsthesia appears to me to have come to stay Mr A E Barker was, I believe, one of the very first to use this method We may look forward, I trust, to hearing the results of his extended experience of the subject ere long

I am, Sirs, yours faithfully

Norwich June 2nd, 1901 S JOHNSON TAYLOR

DARENTH ASYLUM ISOLATION HOSPITAL

To the Editors of THE LANCET

SIRS,—In your list of appointments in THE LANCET of June 1st, page 1581, I notice that I am designated "visiting medical expert to the Isolation Hospital at Darenth Asylum" The correct description of the appointment which I have the honour to hold under the Metropolitan Asylums Board is given in the paragraph on page 1561—viz, *Medical Expert in connexion with Rochester House, Ealing*—which is intended to be conducted as a school and training establishment for 150 of the more educable imbecile children under the care of the board As the announcement in the list of appointments is likely to cause misconception I venture to send this correction

I am, Sirs, yours faithfully,

June 4th, 1901 G E SHUTTLEWORTH

---

"THE IMPORTANCE OF ASEPTIC VACCINATION."

To the Editors of THE LANCET.

SIRS,—Surely a journal with the reputation of THE LANCET owes some explanation to its readers for reproducing in the annotation on aseptic vaccination the often-exposed fable regarding small-pox mortality in the French and German armies. This statement was withdrawn by Dr. W. B. Carpenter, who originally promulgated it in this country. Its falsity was admitted by Lord Herschell's Commission. But the marvellous comparison keeps "popping up again," as the old lady said of Mr. Gladstone. In 1899 Mr. Rider Haggard used it in a little lecture to a conscientious objector, and afterwards withdrew it. The Jenner Society obtained through the Foreign Office an official statement from the French authorities on this subject. In this the estimate that 23,400 soldiers had died from small-pox was stated (as a little reflection would lead one to expect) to be "greatly in excess of the reality" so greatly that the 23,400 was brought down "not to exceed 6000." An estimate worth little at the best has thus suffered an official abatement of nearly 75 per cent. But the story on the authority of your review is still doing service in the newest pro-vaccination literature and THE LANCET has unaccountably given the lie one more start in this country.—I am, Sirs, yours faithfully,

ALEX. PAUL.

⁂ The figures escaped our attention. We regret to have published them as their falsity has been established.—ED. L.

SPANISH BRANDY.

To the Editors of THE LANCET.

SIRS,—We should like to state in your columns, for the benefit of those of the medical profession who are contemplating the use of "Pure Grape Spanish Brandy," that we claim one thing for it only—viz, that of being the matured distillation of grape juice. We state this in order that it may not be construed that we have desired to compare our product to *genuine* Cognac brandy; but what we do wish is that it should be compared, and that favourably, with certain brandies which are bought and consumed by those who cannot pay the price to guarantee their getting the genuine article—viz., *genuine* Cognac brandy—and in consequence obtain, unknown to themselves, clever imitations, in many cases destitute of any grape spirit.

We are, Sirs, yours faithfully,
WILLIAMS AND HUMBERT.

Mincing-lane, London, June 4th, 1901.

"ROYAL ORTHOPÆDIC HOSPITAL."

To the Editors of THE LANCET.

SIRS,—The majority of the executive of the Royal Orthopædic Hospital are still forcing on the sale of the site. It is therefore pertinent to ask what are their reasons for a policy to which so many grave objections have been raised. The arguments against sale have not been answered by Mr. H. H. Marks, although publicly challenged by correspondence and by your article of April 6th, p. 1025. So far from courting publicity Mr. Marks has sheltered himself behind a private letter to the Editors of THE LANCET. Why should there be any mystery about the proposed sale of a freehold property already advanced in price from £28,000 to £38,000 within a few years, and still steadily advancing in value? Any business man proposing to exchange his freehold for a leasehold under such circumstances would be regarded as a candidate for a lunatic asylum. Why does Mr. Marks decline to give a full public statement of the *pros.* and *cons.* of the case in taking a step of such vital importance to an old-established medical charity? Does he, and do the trustees, think it "*desirable*" that the annual deficit of £500 should be increased to £2000 a year or more? Does he, and do they, think it "desirable" that after advertising that the patients have increased by 30 per cent. (this is a compliment by the patients to the work of the *surgical staff*) his intention is to maintain only an equal number of beds in the proposed new building? In fact, as you, Sirs, have said, this matter becomes more and more "a case for publicity" and ample discussion, and this is what Mr. Marks appears to dread. Where, then, is his case?

I am, Sirs, yours faithfully,
June 5th. ANOTHER HOSPITAL GOVERNOR.

THE PAYMENT OF MEDICAL MEN BY THE COLONIAL OFFICE.

To the Editors of THE LANCET.

SIRS,—The parsimony of the Colonial Office is by this time quite proverbial, but it has certainly surpassed itself in respect to the terms offered to the "few doctors" it is asking for duty in the "refugee camps" established in the Orange Free Colony. When "locums" can command from four to seven guineas a week and assistants from three to five, when the War Office is still asking for civil surgeons with pay and allowances of some 25*s.* a day, with free rations, a free return passage, a horse, a servant, and a gratuity of two months' pay, the Colonial Office advertises for medical men to undertake the harassing and depressing duties of a refugee camp for the starvation wage of £1 a day, and even this princely salary commences, not on the day of *embarkation, or even on the day of arrival in South Africa,* but only when the duties are actually taken over. There are no allowances and no rations; and though with a really exceptional liberality a free passage *out* is offered, a discreet and probably economic silence is maintained about the *return.* As a bait the possibility of permanent employment is held out, dependent, however, on "satisfactory service." Permanent employment—where? and as what? When one remembers that the purchasing power of 20*s.* in South Africa is about half, and in some districts only one third, of its home value, the absolute inadequacy of the remuneration offered will, I trust, deter medical men from applying for these posts. Perhaps the services of some of the "*qualified dressers*" advertised for in the last Ashanti expedition might again be utilised? I am, Sirs, yours faithfully,

June 1st, 1901. H. A. D.

"LEGISLATION AGAINST NATIONAL INTEMPERANCE."

To the Editors of THE LANCET.

SIRS,—The discussion of this question seems to have degenerated into a vain and unprofitable attempt to get at the meaning of Dr. Archdall Reid's theories. May I ask you once again to let me state shortly the position of those of us who maintain that the medical profession, with its intimate knowledge of the manifold evils following free indulgence in alcoholic drinks, should join in the effort now being made to amend the licensing laws? The report of the special committee of the Society for the Study of Inebriety has been published and I gather from your summary that the committee is of opinion that some men are born drunkards, some acquire drunken habits (through want of knowledge, evil social habits, &c.), and some have drunken habits thrust upon them (by the force of trade customs and evil environment). I notice, also, that the committee cannot deny that drunken parents of the last two groups are liable to have degenerate children who tend to become criminals, lunatics, and *drunkards.* And, again, that the question of environment is of more importance than that of heredity. Most of us had already arrived at these conclusions some time ago, but we are glad to have the support of the Society for the Study of Inebriety which must, one would think, *now* be thrown in on the side of reform. For if, under suitable conditions as to environment, all or any of us may become drunken the "weeding out" theory can be ignored and the society can join those of us who are in favour not of prohibition (which seems to be Dr. Reid's one idea of temperance reform) but of a serious effort being made to educate public opinion and to bring about a revolution in our methods of dealing with the drink trade. By eliminating private profit from the sale of drink and by doing away with all the attractiveness of public-houses, and at the same time teaching the children in the public schools the truth about alcohol and providing wholesome places of amusement for the people we might hope to create a healthy *environment* and so to make it harder for a boy or girl to acquire drinking habits. I am, Sirs, yours faithfully,

M D., B.S. Lond.

London, May 28th, 1901.

THE ORGANISATION OF THE PROFESSION AND THE RE-ORGANISATION OF THE BRITISH MEDICAL ASSOCIATION.

(FROM OUR SPECIAL COMMISSIONER.)

IT had been announced that a conference on the organisation of the profession would be held at Birmingham during the month of May this year The first conference of this nature met at Manchester 12 months ago. In the interval between these two dates very important alterations in the constitution of the British Medical Association have been proposed As these alterations are framed precisely for the purpose of dealing with the economical and ethical questions which the Manchester conference met to discuss it was anticipated that these proposals would be studied at the gathering which was to take place at Birmingham Such a debate would have been particularly useful because the conference would have consisted in the main, not of representatives of the profession as a whole, but only of those medical men who have taken special interest in the economic problems at issue Thus a technical rather than a general opinion would have found expression and it would be very useful to know the views of those who have practical personal experience of the difficulties involved After such a discussion the task of criticising the proposed new constitution of the British Medical Association would have been greatly simplified Unfortunately, and at the eleventh hour, it was decided not to hold the proposed conference at Birmingham. The reason given for abandoning the conference is that the number of societies who promised to send delegates was too small to justify the trouble and expense which it would entail. This, however, it is maintained, does not indicate any lack of enthusiasm on the part of the societies that participated in last year's conference, but they are desirous first of seeing what form the new constitution of the British Medical Association will finally take In spite of this excuse, and, indeed, in consequence of this excuse, the postponement of the Birmingham conference might be taken as symptomatic of the inherent weakness of the movement in favour of the organisation of the profession This does not mean that the movement will not prosper, but it might be said that its backbone is not firmly set, that it is in a flaccid, gelatinous condition, that it has not yet obtained a firm grip of the situation, nor has it definitely laid the foundations on which it proposes to stand Indeed, as the movement is only some six years old it may still be considered to be in the period of incubation and of hesitation It has not sufficient self confidence and has a fatal tendency to attempt to run with the hare and to hunt with the hounds

There are two courses open for such a movement—that is to say for the organisation of the medical profession The one consists in modestly recognising that this is a matter in which medical men as a class have no experience whatever, and that therefore the medical profession must seek to benefit by the experience which other classes of the community have acquired in successfully organising themselves for the defence of their economic interests The other course is to ignore these teachings of social history, to discover anew what their predecessors have already found out, to learn by experience rather than by example and theory, and to struggle forwards till by dint of blunders and failures the true road to success shall at last have been discovered. If there is one fact that stands out more prominently than another it is that the weaker the organisation the more does it expect to accomplish But it cannot expect to do much out of its own weakness, therefore it looks to other outside influences for help This is a natural law The child expects his parents to provide the food he needs and which he is by himself incapable of procuring Such also is the history of organisations in their infancy They proclaim their needs and then expect the State or other sections of the community to secure for them what they want But if in this respect a new organisation is like a child the comparison breaks down in one very important particular. There are no parents to help the new movement The State, the community at large, is apt to display a heartbreaking and callous indifference towards the newly-born child and thus with organisations infant mortality is even higher than it is with human beings. But if organisations are frequently stamped out in their infancy the potentialities which brought them into existence still subsist and another and similar infant is born at a later period, and this is repeated over and over again till at last one more robust than its predecessors succeeds in living notwithstanding all adverse circumstances Let anyone study to-day the organisation of the medical profession and it will frequently happen that where a medical union is found alive and vigorous there also will be found buried in the ground on which it stands the skeleton of some previous union which had died in its infancy. Take, for instance, the town of Coventry, where the profession is now well organised, a similar organisation was started in 1829 and in 1831, and this, too, to fight against the principal grievance that obtains to day—namely, the abuse of the provident dispensary Indeed, in several localities it is difficult to persuade medical men to organise because they still remember the failure of some previous and similar effort

These facts convey two lessons. First, that new organisations are apt to be nipped in the bud and to die in their infancy; but, on the other hand, if there is a real need of such organisation other efforts will be made at a subsequent date Secondly, the weaker and less experienced these organisations are the more are they apt to look to outside forces for the attainment of their ends Now, in the abandonment of the Birmingham conference, in the hopes reposed on the action of the British Medical Association, in the clamour for stringent legislation and the more active intervention of the General Medical Council, have we not the symptoms of that infantile weakness which relies on parents for food rather than a proof of manly strength capable of winning the means of existence? These facts have to be looked at straight in the face The laws determining the economic evolution of communities are immutable It forms no part of nature's scheme to confer special immunities and privileges on the members of the medical profession If their economic position becomes embarrassed they will have to deal with these difficulties as other members of the community have done This is precisely what they are doing, and they are manifesting the same hesitation, the same weakness, and committing the same blunders as others have done before them The only point where a difference might arise, though there are no signs as yet of its occurrence, is that the medical profession might take greater advantage of the experience acquired by other classes of the community who have been forced by the stress of economic circumstances to form themselves into unions

The course to be followed is simple but difficult Certain economic circumstances have arisen, it cannot be said precisely on what day or at what hour. They have been of slow growth and even to day their presence is but vaguely felt by some and is completely ignored by others. A small minority, however, has acquired a knowledge of the action of these economic forces which, if not altogether new, are daily becoming more evident and more oppressive in their effects upon the medical profession This small minority has not been brought into existence by any one cause but by a multiplicity of causes, therefore each individual understands better that phase of the question which affects him personally This uneven distribution of knowledge is a source of great weakness, because it tends to split up the profession into different organisations instead of uniting it in one body Thus a certain number of practitioners are keenly alive to the evils of hospital abuse and some among them have consequently joined together in forming the Hospital Reform Association Others, on the other hand, feel the weak position of the practitioner should he have the misfortune to meet designing, unscrupulous people who might endeavour to ensnare him with a view to levying blackmail, &c Hence we have the Medical Defence Union and the London and Counties Medical Protection Society. Others, and they are the greatest number, realise that it is the provident dispensaries, the medical aid insurance companies, and the friendly societies that are the worst obstacles, and thus we have the formation, as at Coventry and Eastbourne, of Public Medical Services managed entirely by the medical men themselves Then there is yet another set of practitioners who complain of the competition of medical men against medical men and are bitter against "sixpenny doctors," and these practitioners are most anxious to form medical ethical societies But all these grievances are different manifestations of the one fundamental cause, the evolution of economic forces. They can only be met by action of a politico-economic character based on elevated ethical principles. The water has overflowed the river-wall. To deal with one grievance, to raise the embankment at one particular spot, will not prevent the flood; the embankment must be strengthened from one end to the other. Consequently the organisation to be formed must be prepared to deal with every phase of the economic problem at issue. Such an organisation must be composed of men who are capable of, and who have the knowledge necessary for, accomplishing the task. For this it is necessary to organise a widespread system of education and it will take a long time to accomplish this work. But man in his weakness and impotence longs for a short cut so as to end more rapidly his wearisome journey towards better destinies. Hence the tendency to gamble rather than to toil for the slow accumulation of fortune.

The practical question which has now to be examined is whether the proposed alteration of the constitution of the British Medical Association is a genuine step forward in the work of organising the profession for the defence of its economic interests, or whether it is but one of those deceptive short cuts which, instead of leading sooner to the end, only result in disappointments. This is a question that cannot be readily answered, because the result will depend so much, not on the method of organisation, but on the action of individuals. As for the method of organisation it presents obvious dangers. Will the energy and perspicacity of those most concerned suffice to overcome these dangers? No one can tell, for men totally unknown to-day may spring out of the ranks and lead with such skill that every obstacle will fall before them. The policy may be described as that of permeation and this is a double-edged weapon, for those who embark on such a mission never know whether they are going to permeate or whether they are going to be permeated. There are in England from 40 to 50 societies of medical men that are, comparatively speaking, ripe for the economic struggle, that do possess some knowledge of the economic problems at issue, that have very similar programmes, and that have an approximately clear conception of what should be done. This is a small beginning. These societies are young and they manifest some of the weaknesses described above and represent but an infinitesimal minority of the profession. But their influence is much greater than their numbers imply, for they alone are at least partially conscious of their class interests and they alone are to some extent disciplined. Will this small amount of leaven suffice to raise the whole profession, or will the apathy, the indifference, the ignorance of the great mass destroy these germs of progress? Had they kept apart, working only with those who were at one with them, they would not in any case be crushed, but their progress would be very slow. The existence by their side of so great an organisation as that of the British Medical Association is undoubtedly a very strong temptation. There are the men, thousands and thousands of them, there is the social influence, there is the money; if they would only all fall in and march as one man, how easily, how quickly, would the end be attained. This looks like a short cut, a very tempting path to follow. But will it be possible to move this great and comparatively inert mass? That is the problem.

Efforts are to be made to infuse new vitality into the branches of the British Medical Association, to render the general meetings more representative, and, above all, to institute a system of delegateship which shall be a real parliament of the profession, the decisions of which shall be binding on the executive of the association. But the more the profession is fully and adequately represented the more incoherent and contradictory will such representation become. Nothing could be more misleading than to imagine that the profession, as a whole, understands its economic position or possesses any distinct conception of what it needs and how this desideratum is to be obtained. Such knowledge exists, and this only to a limited extent, among the members of those few medical unions and guilds formed during the last six or seven years to deal exclusively with economic and ethical questions. It would be a grave mistake to sink such organisations, to allow them to be swallowed up by a larger body that is not so well versed in the points at issue. That these really militant and more competent bodies should be represented at the meetings of the larger organisation so as to strive to stimulate the more numerous but more inert body is all well and good. Such propaganda will doubtless bear fruit. But the truly militant, class conscious members of the profession who are organised to deal with the economic problem, however few they may be and however weak they may seem, must ever be ready to stand apart, faithfully adhering to the whole of their programme. Common-sense indicates the wisdom of joining with others so as to realise portions of their programme, but they should never allow themselves to be merged in a bigger body which has not yet accepted the whole of their programme. If these small but truly conscious bodies can play the part of the tail that wags the dog nothing better can be desired, but they must be prepared to stand independently on their own ground when they find that the dog attempts to wag them.

The question after all is extremely simple. There are economic forces developing that seriously menace the position and good name of the medical profession. A few medical men who may be qualified as pioneers have not only studied these economic problems but have formed organisations and have practically dealt with some of the difficulties. These pioneers have acquired a technique, the technique of economics as they affect the medical profession. They are qualified medical economists; their mode of procedure must not be swept away by a majority composed of unqualified voters. That the ignorant should be persuaded, that they should be taught, and that every opportunity should be given them to acquire knowledge, is most desirable, but that they should govern by their votes while they still ignore the points at issue, that cannot be admitted. Every effort must be made to dispel this ignorance, but while it still exists those organisations that are better informed must persevere in their mission, must maintain their independent existence. They are the vanguard of the army, they must keep well to the fore. The fact that they are not numerous is an insufficient excuse to justify them in occasionally falling back on the main body of the army. This may be done temporarily to attack in force some one particular point, but, this point carried, the vanguard must again separate itself from the main body and forge ahead.

GERMAN CONGRESS OF INTERNAL MEDICINE.

(FROM OUR BERLIN CORRESPONDENT.)

(*Concluded from p. 1367.*)

Acute Myelitis.

PROFESSOR VON LEYDEN (Berlin) read a paper on this disease, discussing it from the clinical point of view. He said that there were four forms of the disease: transverse myelitis, disseminated myelitis, poliomyelitis, and compression myelitis. Inflammation, softening, and hæmorrhage of the spinal cord were the principal anatomical lesions of myelitis. With respect to the etiology it was very probable that the disease was caused by infection; the majority of the cases were, in fact, subsequent to infective diseases, such as influenza, enteric fever, rheumatic sore-throat, phlegmon, &c. He had observed cases of myelitis following gonorrhœa, tuberculosis, and syphilis. Apart from infection myelitis might be caused by various injuries. The clinical symptoms differed according to the localisation; there was a dorsal, a cervical, and a bulbar form. The disease might develop either suddenly or gradually and by intervals Myelitis might advance to the bulb and so constitute an immediate danger to the patient's life, or it might spread in a transverse direction. Neuro-paralytic symptoms, such as paresis of the bladder and rectum, bedsore, &c., appeared somewhat early and made the prognosis unfavourable. The disease, as a rule, terminated fatally, but in some cases recovery had been observed. Sometimes the disease became chronic. Good nursing of the patients was especially necessary.

Professor REDLICH (Vienna) discussed the pathological anatomy of myelitis. He said that the late Professor Charcot was of opinion that in poliomyelitis the ganglia alone were affected; this, however, was the fact only in slight cases. In the great majority of cases not only the ganglia but also the other parts of the spinal cord were involved. In disseminated myelitis of the young there was an infiltration of the grey substance In other cases the disease was characterised by a degeneration and necrosis of the nervous substance Meningitis was not unfrequently combined with myelitis With respect to the etiology he said that bacteria had been detected in but few cases They were spread by the vessels, the subarachnoidal and the central canal The essential cause seemed to be the action of toxins The etiology was not yet by any means clear and must be studied further by the aid of puncture of the lumbar arachnoid

Professor VON STRÜMPELL (Erlangen) pointed out that myelitis might be caused by bacteria as well as by toxins In two cases in which lumbar puncture was made staphylococcus albus was found in one, but in the other the fluid was sterile

Dr SCHULTZE (Bonn) said that a new growth of the spine sometimes gave rise to the same symptoms as myelitis

Professor VON KAHLDEN (Freiburg) said that a degenerative lesion of the parenchyma was the primary, and degeneration of the vessels the secondary, lesion In poliomyelitis the ganglia were first affected

Dr RITTER (Berlin) reported six cases of myelitis in children He concluded from his investigations that they were caused by ptomaines

Epidemic Cerebro Spinal Meningitis

Dr JÄGER (Königsberg) said that this disease did not by any means always appear in the epidemic form, but that isolated cases might occur throughout the whole year, as had been found by bacteriological examination In all suspected cases even when the disease was not prevalent the arachnoidal fluid should be examined bacteriologically The statistics of the disease were still insufficient The enormous spread of cerebro-spinal meningitis in densely crowded districts in America, as, for instance, in New York, Massachusetts, &c, was very striking and the disease was very probably imported from there directly to Hamburg or indirectly through Copenhagen where epidemics are very frequent also

Alterations of the Blood in Rabies

Professor COURMONT (Lyons) read a paper on the polynuclear neutrophile leucocytosis which, according to his researches, is characteristic of this disease He has found that one of the first symptoms of rabies was an enormous increase of the leucocytes In the lungs of animals often 85 per cent of polynuclear leucocytes were present He said that the significance of this symptom could not be over estimated, for there was no rabies without polynuclear leucocytosis This observation was of great importance in relation to early diagnosis

Serum Diagnosis of Tuberculosis

Professor COURMONT also gave an account of a method used by Dr Arloing and himself for the purpose of ascertaining the presence of tuberculosis by bacteriological examination of the blood According to Dr Arloing tubercle bacilli caused the serum of the blood of tuberculous persons to become cloudy This application of serum diagnosis was very much used in the country of its originators, but had not proved trustworthy in Germany Dr Courmont said that only tubercle bacilli of great virulence gave this reaction When the virulence of a culture was verified day by day the method never failed as was shown by a long series of experiments made on animals in Lyons

Mortality of Pneumonia

Dr HAMPELN (Riga) read some statistics of the mortality of pneumonia He had found that the mortality differed considerably according as the patients were treated at home or in a hospital, being much greater among the hospital patients He was of opinion that the higher death rate was due to the effects of the journeying from the patient's home to the hospital, a danger which ought to be met by the employment of properly constructed ambulances

Dr GEORGE MEYER (Berlin) pointed out that as far as the greater towns of Germany were concerned the arrangements for the conveyance of patients were, as a rule, satisfactory

Other papers read before the Congress dealt with the following subjects the Skiagraphy of the Heart, by Dr MORITZ (Munich) and Dr LEVY DORN (Berlin), Pulmonary Syphilis (preparations shown), by Professor VON HANSEMANN (Berlin), Febris Hepatica, by Dr MÜNZER (Prague), the Synthesis of Uric Acid in the Animal Organism, by Dr WIENER (Prague), &c Professor Naunyn (Strassburg) was elected President of the next congress which will be held at Wiesbaden

MANCHESTER

(FROM OUR OWN CORRESPONDENT)

Heaton Park.

IT seems not unlikely that the Corporation of Manchester will repeat the fiasco they succeeded in accomplishing over the Trafford Park Estate As may be remembered, this valuable property was snapped up by a wide awake syndicate while the corporation was soliloquising "to be or not to be" It may be eminently respectable for civic authorities not to be wide awake, but it is unfortunate when the multitude suffers for it Manchester is growing rapidly, extending amœba like, and absorbing every green spot she touches Her weakly, stunted, pallid population of workers lives under conditions not favourable to healthy development It is therefore desirable that the open spaces within reach of the city should not be covered with bricks and mortar, for even if there are many who will not directly visit them they will be benefited by the healthful breezes which sweep over such tracts of land as Heaton Park and carry freshening influences into the streets and lanes of the city This park, of 650 acres, together with the hall and other buildings, has been offered to the corporation for £230,000 The sub committee having the matter in hand was prepared to recommend the corporation "to pay £190,000 for the park, with its buildings, walls, and minerals, and such fixtures and fittings as might be agreed on" This has been declined, Lord Wilton and his advisers considering that the price asked was a low one The sub-committee thought that £190,000 was a full price The week before last the Parks Committee had the matter again under consideration, when two propositions were submitted and rejected The first was that £210 000 should be offered, and the other that the amount should be £200 000 The council at its monthly meeting to morrow, June 5th, is to consider the question again A decision must be arrived at by June 12th, as Lord Wilton's offer is only open till then This is the last opportunity of acquiring a large open space in the immediate neighbourhood of Manchester All have gone but Heaton Park, and if this goes it will be a matter for never-ending regret

Proposed Small pox Hospital for Warrington

An inquiry was held at Warrington on June 1st by Dr Manby, Local Government Board inspector, into the application of the Warrington Corporation for sanction to borrow £9979 for the provision of a small pox hospital at Great Sankey, and £8702 for the extension of the borough infectious diseases hospital The Mayor in his evidence referred to the serious lack of accommodation during the small pox epidemic of 1892-93, which "carried away many valuable lives, laid large numbers of families under serious financial obligations, and cost the borough over £10 000" The infectious hospital was occupied with fever cases, and an old foundry had to be fitted up as a temporary hospital Since that time sites have been visited, and one was decided on, but for various reasons had to be abandoned A provisional agreement has been made to purchase 11½ acres at Great Sankey for £1750 The residents, of course, as all residents do, object to the scheme, mainly, it is said, on the ground that the site is unsuitable, but also because of the danger of infection "from the hospital sewage effluent and the foul air which would be given off by the hospital when in use" In answer to the inspector the opponents of the scheme said they had no alternative to suggest With our semi compulsory, semi voluntary dealing as to vaccination a small pox hospital should be provided not only for Warrington but for many other places

Proposed Cooperative Convalescent Home

It speaks well for the intelligence of the northern section of the Coöperative Union, which comprises the counties of Northumberland, Durham, Cumberland, Westmorland, and the North Riding of Yorkshire, that they should consider seriously the question of providing a convalescent home for their members One idea was to build a home at Rothbury at a cost of £10 000, but in the meantime the Shaws Hotel at Gilsland with adjoining property has been offered for sale by the proprietors to the northern section of the union At a meeting held at Gilsland on June 1st it was agreed that a report on the whole matter should be presented to the societies If the scheme should be carried to completion it is to be hoped that the medical arrangements will be dealt with intelligently. But this north-country association has not been the first in the field. The Coöperative Wholesale Society, which comprises 11,000 retail societies with more than 1,000,000 members, will almost immediately open Roden Hall, near Shrewsbury, as a convalescent home with 40 beds. Miss M. I. Twigg of Walkden, near Manchester, a local nurse, is to be the first matron.

Bequests to Stockport Charities.

By the will of the late Mr. Thomas Hardcastle Sykes £1000 has been bequeathed to the Stockport Infirmary and £500 to the Stockport Institution for the Blind, Deaf, and Dumb.

June 4th.

WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Swansea Sewage.

IT has been recognised for a long time that a main sewer to deal with a portion of the sewage in the lower part of Swansea is urgently needed and various schemes have from time to time been discussed by the corporation. These have at length been focussed into three definite proposals, in one of which the outfall is in the town at the pier-head and in the other two at Brynmill, a short distance from the more densely-populated portion of the town but quite close to the sands and promenade. The outfall at the pier-head and in one of the Brynmill schemes discharges the sewage into the sea untreated, but in the alternative Brynmill scheme it is proposed to provide for a septic tank between the termination of the sewer and its outfall, though the effluent is not to be subjected to any filtering process or to be made to pass over land. The members of the town council have been very evenly divided in their opinions as to the merits of these three projects, the cost of which does not vary more than a few thousand pounds, for the engineer's estimate in each case is between £70,000 and £80,000. The water and sewers committee of the corporation recommended the adoption of the Brynmill scheme minus the septic tank, but on April 16th the council refused to accept this recommendation and a resolution was carried by 15 votes to 14 in favour of the pier-head scheme. At the same meeting an amendment to this resolution was carried by 17 votes to 12 approving the Brynmill outfall with a septic tank. The advocates of the pier-head outfall thereupon gave notice of motion to rescind this resolution, and a special meeting of the council was held on May 24th for the purpose of coming to a final decision. In the meantime the borough engineer and the medical officer of health (Mr. Ebenezer Davies) reported fully upon the whole question and each official was in favour of the pier-head scheme, the engineer laying stress upon the fact that by its adoption he could more effectually deal with the drainage from a large number of low-lying houses that at present are frequently flooded, and the medical officer of health was evidently influenced in the advice he gave by his desire to preserve the Brynmill sands from sewage contamination, and he very properly insisted that a septic tank alone would not of itself prevent this contamination, but that the bacterial method of purification if adopted at all should be carried out in its entirety. In spite of the advice of their responsible officers the town council decided by 20 votes to 11 to carry the sewer to Brynmill and to discharge the sewage after it has passed through a septic tank on to the sands at low water. There still remains the engineering inspector of the Local Government Board to be reckoned with, and hitherto the policy of the Board has been to require provision to be made for the treatment of the effluent from a septic tank before sanctioning expenditure upon works of this nature, though it is possible that there may be in the local conditions at Swansea circumstances warranting a departure from this policy.

Antitoxin in Poor-law Practices.

The board of guardians of the Pontypridd Union have decided to place antitoxin upon the list of expensive drugs to be paid for by the board and not by the medical officer to the union, and has also decided to reimburse Mr. Jenkin Jenkins, one of the district medical officers, the cost of the antitoxin which he has used in the course of his parish practice during the past few months. Poor-law medical officers are not paid such extravagantly large salaries that they can very well afford to use such an expensive remedy very freely, and diphtheria has been so prevalent in the Pontypridd district during the past year that the necessity for the employment of the serum must have arisen very often indeed.

Western Counties Idiot Asylum, Starcross.

The annual meeting of the subscribers of the Western Counties Idiot Asylum was held on May 25th, under the presidency of Prebendary the Earl of Devon. The report stated that at the end of December last the institution contained 269 inmates, 182 boys and 87 girls. During 1900 there were 44 children admitted; 21 were discharged and four died. The financial statement showed an income of £7812 and a favourable balance of £305. It was unanimously resolved that the title of the institution should be changed to the "Western Counties Training Institution for the Feeble-minded." The change of title seems a wise one, as the institution only deals with those cases of defective intelligence in which there is a reasonable hope of development and improvement.

June 3rd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Edinburgh Town Council and Bacteriology in Connexion with Public Health.

A GOOD deal of feeling is being displayed in several quarters in Edinburgh in connexion with advances which have, as is generally understood, been made by the University to the city authorities with a view to having the bacteriological work connected with public health transferred to the new public health laboratories of the University. To understand the feeling which has arisen it is necessary to state that for years the laboratory of the Royal College of Physicians of Edinburgh did a large amount of reporting on material sent to them by Fellows of the College and their friends, and did this without fee of any kind. Sputum, swabs from cases suspected to be diphtheria, and more recently blood to be examined for Widal's reaction were thus dealt with. The work necessarily grew in amount, and as the laboratory is more a physiological than a pathological one there was a good deal of complaint that it was over-weighted with this reporting work. The demand and indeed the necessity for reports became more imperative and it was thought that work bearing so importantly upon the well-being of the community ought to be done, or at least paid for, by the city. Then followed negotiations between representatives of the College of Physicians and the Public Health Committee of the Town Council. The outcome of these was that the College laboratory was to continue to report and that the city was to pay for each report; but the material for examination was to go through the hands of the medical officer of health of the city, by whom it was to be transferred to the College laboratory. Then it was arranged, if my memory is correct, that part of this reporting was to be done at the City Hospital. Matters got mixed up, and the general impression was that the city was to take over the work and that it was to be done in connexion with the City Hospital. Meanwhile, the University steps in and offers to do this work for a consideration, amounting, it is understood, to some hundreds per annum. The upshot of it all is that there are now three plans before the city authorities—first, to continue to employ the College laboratory; secondly, to keep a laboratory of their own; and thirdly, to hand over the work to the University. The Public Health Committee feel that they can hardly take the work from the College and give it to the University, and yet either would be cheaper than running a civic laboratory. The College is sensitive in view of the work it has already done for the city; the University is always crying, "Give, give"; the public want the cheapest method consistent with efficiency; and some select spirits think that the University department ought not to be hampered with work of the kind, that the professor should be free for original research, and that the professorial emoluments ought not to be increased in this way. Such is practically the position of affairs. One remark it is safe to make and that is that the multiplying of laboratories is a mistake when the great want is money to pay men to work in those already existing. Mr. Carnegie would do incalculable benefit to Scotland if he provided means for this purpose.

Aberdeen Medical Staff Corps

On June 2nd the members of the Aberdeen volunteer company Medical Staff Corps mustered in the grounds of Gordon's College and thereafter attended church parade in St. George's-in-the-West Parish Church, when the Rev. James Smith delivered an eloquent address. The detachment was under the command of Surgeon Captain J. Mackenzie Booth, M D. Aberd, and there were present on parade nine staff sergeants and 94 rank and file.

June 4th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal Medical Benevolent Society of Ireland.

THE annual meeting of the Royal Medical Benevolent Society of Ireland was held on June 3rd at the house of the Royal College of Surgeons in Ireland, Mr. Thomas Myles, the President of the College, being in the chair. Sir John William Moore read the report, which contained copies of the message of condolence sent on the occasion of the Queen's death and His Majesty's letter in reply. Sir George P. O'Farrell moved a resolution of thanks to the committee and officers of the society for their services Sir Charles A. Cameron congratulated the society on its present satisfactory financial position and observed that the expense of administering the fund amounted to only 5 per cent. of the receipts.

Death of Mr. J. K. Gibson, L.R.C.P. & S. Edin.

I have to announce with great regret the death of Mr. J. K. Gibson of Randalstown, co. Antrim. He had felt unwell and was at Belfast on a visit to his cousin, Dr. W. Gibson, J.P. On May 25th, quite suddenly, he was seized with acute illness which culminated in an attack of pneumonia from which he died on May 29th. Mr. Gibson was a young medical man of promise. After qualifying he was for two years house surgeon in the Belfast Union Infirmary, and shortly afterwards he began practice in Randalstown, where, by his tact, judgment, and kindliness, he had built up a good private practice. He was buried at Randalstown on May 31st, a large concourse attending the funeral, a sufficient evidence of the respect that was entertained for him.

The New Equipment Scheme of Queen's College, Belfast.

At a meeting of the Executive Committee of this scheme, held on May 29th, it was announced that, including Dr. P. Redfern's subscription of £500, additional sums amounting to £2775 had been promised.

Ulster Branch of the National Association for the [illegible]

He[illegible] the Town [illegible] large attendance. The Marquis of Dufferin and Ava, who presided, in an interesting speech drew attention to the fact that the mortality from consumption in Ulster was double that of Lancashire and was quadruple that of the healthier counties of Great Britain. Dr. A. P. Hillier (London) delivered an address in moving the following motion:—

> That this meeting appeals to those interested in their fellow creatures to provide a sanatorium on a large scale for the [illegible] suffering from consumptio[illegible] towns and rural districts t[illegible] efficiently inspected, recon[illegible] and Cowsheds Act, and ca[illegible] prevent spitting in mills, f[illegible] companies to put up notice[illegible] and stations.

This was seconded by Professor J. W. Byers, President of the North of Ireland Branch of the British Medical Association, who pointed out that in Belfast about one in every seven deaths was from tuberculosis of the lungs. He thought that the measures for the prevention of tuberculosis might be classified under four heads; (1) the education of the public as to the causes and means of prevention [illegible] (3) [illegible] sup[illegible] [illegible] moved that the name of the association be altered to "The Ulster Branch of the National Association for the Prevention of Consumption." This was seconded by Dr. J. Stewart (surgeon to the gaol) and passed. Office-bearers having been appointed a vote of thanks was accorded to the Marquis of Dufferin and Ava who, in reply, said that he had "seldom had the good fortune to attend a meeting where the speeches had been more to the point or more full of interesting and effective matter. What had been said was calculated to produce the most practical results."

Rainfall in May in Ulster.

The last month (May) has been, it turns out, an exceptionally dry one, only 1 65 inches of rain being registered falling on nine days, as compared with 16 days' rain and a depth of 3 3 inches in May, 1900. The greatest fall in one day was on the 30th, 0 48 inches being the amount. In the five months of 1901 rain has fallen on 70 days to a depth of 12 28 inches, while in the corresponding period of last year there were 82 wet days, with a total depth of 13 86 inches of rain.

A New Experiment in Public-houses.

A new company—"The Ulster Public-houses Trust Company, Limited"—has been established in Belfast the object of which is to apply to inns a principle of administration which will secure that they shall be managed as a trust in the interests of the community and not for private profit. Only the best drinks that can be obtained in the open market will be sold. It will not be in the interests of the manager to push the sale of intoxicants; he will be paid a fixed salary with commission on the sale of food and non-intoxicants and will receive no commission on the sale of alcoholic drinks. The inns are to be refreshment houses and not "drinking-bars." Food and non-intoxicants will be supplied as readily as intoxicants and during the same hours. The surplus profits, after allowing a sufficient sum for depreciation, reserve, and interest, not exceeding 5 per cent. on the invested capital, will be administered by carefully selected trustees for the benefit of the community. These methods have already been tried in England, but this is the first time that they have been introduced into Ireland, the idea being that reform, rather than abolition, must be the aim of sound temperance policy. The first inn, "The Crown and Shamrock," was opened last week in the neighbourhood of Belfast at a village called Carnmoney, a convenient cycling run from Belfast, and it is hoped that this new experiment will be a success. Another inn conducted on similar lines is, I hear, to be opened shortly in Belfast.

Health of Belfast.

Between April 21st and May 18th, 1901, 300 cases of zymotic disease have been notified—viz, 129 cases of typhoid fever, 83 of simple continued fever, 30 of scarlet fever, 83 of erysipelas, 15 of diphtheria, six of typhus fever, four of membranous croup, three of small-pox, and two of puerperal fever. There were 76 deaths from zymotic disease, 103 from phthisis, and 105 from diseases of the respiratory organs. The annual death-rate was 21 1 from all causes; for children under one year old it was 4·4, and for persons of 60 years and upwards it was 3 6 per 1000 of the population. Three cases of small-pox occurred and one death—a woman who came from Paisley a week previously to becoming ill. All the cases were promptly isolated and it is most satisfactory to report that the disease has been stamped out. Considering the close intercourse between Belfast and Glasgow it is remarkable and fortunate that Belfast has so far escaped so well. In the discussion in the city council on this report of the public officer of health one of the members complained that the zymotic death-rate of Belfast was far too high. He thought that measles should be a notifiable disease and suggested that something should be done in the way of voluntary notification of tuberculosis.

Death of Dr. W. T. A. Scanlan, Senior Assistant Medical Officer of the Cork District Lunatic Asylum.

The announcement of the death of Dr. Scanlan came as a painful surprise to many of his friends early last week. He was attending to his ordinary duties on May 24th, but that evening symptoms of acute obstruction of the bowels developed themselves. Several of his medical brethren came to his assistance and laparotomy was performed on the 26th, but he succumbed the following day after an illness lasting barely three days. Dr. Scanlan, who was only 33 years of age, was cut off in the prime of life His genial, kindly manners endeared him to all with whom his duties brought him in contact, and the large gathering of representative citizens present at his funeral testified to the high esteem in which he was held. He was educated at the Queen's College, Cork, and displayed talents of an order calculated to reflect credit on his native city. His funeral was one of the largest which has passed through Cork for a considerable time. It was attended by a large number of clergymen of various denominations. Forty of the uniformed attendants of the asylum marched in the procession, followed by 30 of the female attendants. The medical profession was very largely represented and several of the governors of the asylum were there to testify by their presence their high appreciation of the manner in which Dr. Scanlan had at all times discharged his onerous duties. It was well known to his medical brethren and amongst the public generally that he was engaged to be married at an early date to one of the lady nurses of the asylum, and that fact lent much pathos to the all-too-early cutting off of a brilliant career. Prior to the starting of the mournful *cortège* the asylum band assembled in the little chapel of the institution and played the Dead March in *Saul*. Several public bodies, amongst them the Cork Medical and Surgical Society, passed votes of sympathy with the relatives of the highly respected and esteemed deceased.

June 4th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

League for the Repression of Syphilis.

PROFESSOR FOURNIER has just made the preliminary arrangements for the foundation of a league against the propagation of syphilis and venereal diseases—a league for which he particularly invites the support of medical men. In a lecture delivered at the reopening of his course he reminded his hearers of the urgent necessity for further attention to the prophylaxis of syphilis, which for the last 10 years has been increasing in an alarming degree, since it is found in the proportion of 15 per cent. among hospital patients. Moreover, the manifestly growing tendency of syphilis to result in parasyphilitic conditions, such as tabes, general paralysis, and buccal leucoplasia—a disease predisposing to cancer—gives it a serious aspect which it did not formerly possess. Syphilis is, therefore, like tuberculosis and alcoholism, a scourge against which it is urgently necessary to protect society. The measures on which the league will rely will be of three different kinds—namely, moral and religious, administrative, and medical. The moral and religious part of the programme will aim at the purification of morals and the encouragement of early marriage and will be committed to the priest, to the Protestant clergyman, to the rabbi, and to persons of both sexes engaged in educational work, so as to counteract the pernicious influence exerted on the young brain by novels and theatres. In the administrative direction the league will endeavour to bring about a strict supervision of prostitutes who display themselves in public, because the granting of permission to entice persons as they walk along the street and eventually to infect them with syphilis is as unreasonable as the granting of permission for a mad dog to be at large. This interference of the authorities is the more legitimate because venereal diseases are especially observed among unregistered prostitutes, even in a proportion which may rise as high as 48 per cent., according to the most recent statistics of M. le Pileur. More than this, syphilis attacks persons who do not voluntarily expose themselves to it, such as women living connubially, wet-nurses, and children, whose only protection lies in the measures taken by the authorities. But in this work of protection the hospital must be in place of the prison and the policy adopted must be humanitarian. Another object of the league will be the closing of a certain class of places where beer and wine are sold and which are dangerous centres of infection. The unfortunate women in these establishments ought not to be sent to prison but ought rather to be admitted to charitable homes and training schools. Medical prophylaxis will be realised by the creation of dispensaries and the giving of advice at all times, so as to avoid the conditions which too often prevent patients from resorting to hospitals, such as crowding, loss of time, commingling of different classes, and the public acknowledgment of illness. In these dispensaries medicines must be given free of charge, for it is found that patients may sometimes be compelled by poverty to neglect the treatment prescribed for them and to develop irremediable lesions. It will also be necessary to watch over the prevention of syphilis in the army and to undertake the still more delicate and important duty of instructing the public on the subject of venereal diseases and the mischiefs which they cause. In presence of such a scourge there must be no hesitation in departing from the *reserve* imposed by modesty—a reserve which is particularly dangerous. Notwithstanding the obstacle presented by the state of current public opinion youths on reaching their eighteenth year ought to have the requisite knowledge imparted to them, and meetings for this purpose ought, if necessary, to be held in the *lycées*. The question whether similar instruction should also be given to young girls is a more delicate one, but Professor Fournier leans towards the view that it may be answered in the affirmative. The business of the first meeting of the league will be the discussion of this question and the expression of a formal opinion.

Music and Surgical Anæsthesia

At a meeting of the Academy of Medicine, held on May 14th, M. Laborde explained the part which he thinks that musical sensations are destined to fill in surgical anæsthesia. It is a well-known fact that patients under the influence of nitrous oxide often exhibit psychical manifestations of terror accompanied by screams and struggles Having ascertained that these phenomena of terror always have for their origin external noises of greater or less intensity, such as those caused by vehicles, M Drosner, a dentist, has had the idea that during anæsthesia harmonious sounds produced by a phonograph might be substituted for casual noises. Of course, no sensation of pain was experienced during the dental operations performed under these conditions, but in addition to this all the patients asserted that during the whole of the proceedings they were conscious of the charm of the music and were free from dreaming and nightmare. These results may be easily explained. The question, in fact, is one of a psycho physiological influence exerted directly on the centres for musical sensations, and these latter modify in a favourable manner the psychical action of the anæsthetic, substituting the influence of a musical dreamy state for that of a terrifying one. This method may, perhaps, be extended to surgical anæsthesia in general, even in combination with anæsthetics such as chloroform and ether, the action of which on the cerebral and psychical centres often produces, as is well known, manifestations which disturb the surgeon in his work.

An Injustice to the Medical Profession in France.

The medical profession in France, upon which encroachments have so often been made by recent legislation, is threatened with a new danger. The Government has increased the burdens of medical men by raising the fees payable for their *patente* and by taxing their carriages and consulting-rooms as if they were outward and visible signs of affluence, and now it seems that the Government is about to adopt a policy which will have the effect of reducing the number of the patients upon whom medical practitioners depend for their livelihood. By each new law and at each administrative appointment it is stipulated that medical attendance shall be given free of charge. The Government sees that a few eminent surgeons make large fortunes rapidly—a thing which happens in every part of the world—and on this ground it appears to assume that all the medical men in the country, even those who practise on a modest scale in villages and find it difficult to live by their profession, are possessed of ample private means. The Chamber of Deputies has just supplied an example of this mistaken view. The Minister of War had observed with regret the increasing diminution in the number of the military officers of the reserve; resignations were becoming more frequent every day, while at the same time applicants for the vacant places were fewer. The real reason of the distaste which the officers of the reserve feel for the service depends, as everybody knows, on the useless annoyances that the Government inflicts on them by calling them out too often for manœuvres without taking into account the accompanying interference with their occupations in private life and by placing them in positions which expose them to the rudeness of the professional officers who treat them without any consideration, by frequently ordering useless and expensive changes of uniform, and finally by treating them unjustly in the bestowal of crosses and awards which the law has set apart for the officers of the reserve and which the Minister diverts from their proper destination for the benefit of the professional officers In place, however, of acknowledging these well founded grievances of the officers of the reserve and abating them, the Minister has endeavoured to create in favour of the officers of the reserve new advantages which may retain them in the service. But it is at the expense of the medical profession that the new privileges have been created, for it has been decided that the officers of the reserve and their families shall be entitled to receive free medical attendance from the surgeons of the regiment stationed in the towns where they live. The mutual aid societies and the law as to free medical attendance have disposed of the patients who used to pay small fees, and the new order means that from 30,000 to 40,000 families, all belonging to the well-to-do middle class, will now spend nothing on medical advice, a change which will be severely felt by many practitioners The medical unions are protesting energetically against this new privilege, with which is combined the right of travelling over all railways at very reduced fares. The Chamber has not yet been called on to discuss the proposal, but the time is not far off, and there is nothing to show that the unlucky medical men will not once more be victims of Governmental reforms.

June 3rd.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Proportion of Physicians to the Population

THE census relating to physicians indicates the possibility, if not the actuality, of overcrowding in the medical profession. It was found in the census year that there was one registered physician to every 655 people in the United States That this number is in excess of the need is evidenced by a comparison with Germany, where in 1898 there was only one physician to every 2114 inhabitants, or relatively about one-third as many as in the United States. Medical men are more plentiful proportionately in some States than in others; in California there is one physician to every 416 inhabitants and in North Carolina one for each 1189 of the population. Even in States geographically connected and similar as to conditions there is a wide disparity as to the number of practitioners. The State of Michigan has one medical man to every 570 of the population, but in Wisconsin there are 936 inhabitants to each physician, and in Minnesota there are 1004 people to each practitioner. Massachusetts has more physicians proportionately than the adjoining States of Connecticut and Rhode Island; New Hampshire and Maine have much the same proportion as Massachusetts; but Vermont finds employment for a considerably larger number of medical men.

Excessive Use of Narcotics.

Professor Grinnell of Burlington, Vermont, has been making an investigation into the use of narcotics in that State. He found that in the regular drug stores and in 160 of the 172 general stores of the State there are sold every month 33,000,000 doses of opium, besides what is dispensed in patent medicines and besides what the medical men prescribe, which gives one and one-half doses of opium to every man and woman in the State above the age of 21 years every day of the year. By dose he means one grain of opium, one-eighth grain of morphine, one-half ounce of paregoric, and 20 drops of laudanum. The amount consumed each month means a half dose for each man, woman, and child in the State every day of the year. This statement is based upon facts and is conservative; where information was refused no estimate was made, and the scale of the consumption would be larger if all the sales could be tabulated. No explanation of this undue use of narcotics is offered, but it is ascribed in large part to the difficulty of obtaining intoxicants in towns where the prohibition laws are enforced.

A Plea against Ambidexterity.

In an address before the Illinois Society for Child Study Professor Smedley, who is director of the Chicago Department of Child Study and Pedagogic Investigation and who holds views radically different from those entertained by many physicians, said that teaching ambidexterity was teaching contrary to the laws of life When they went beyond nature and attempted to teach left-handed people to use the right hand they were making a mistake. Ambidexterity was likely to interfere with a child's best method of development and might cause the loss of speech. In his investigations on the subject he had discovered that a surprisingly large number of the children whose speech was defective were left-handed. Out of the 30 children of defective speech who came to the laboratory 12 were left-handed—that was, about 40 per cent. Several said, "When my mother learned that I was left-handed she made me carry my arm in a sling." Professor Smedley concluded with the remark that interference with the free use of the left hand interfered with the development of the power of speech, and that he believed that strong unidexterity is the natural and ideal condition.

Reckless Driving of Ambulances.

New York streets are now so frequently the scene of accidents from carelessly driven ambulances that protests are often made against them. A recent number of a medical journal contains an article by a local physician, relating an occurrence which he saw, as illustrating the danger of reckless driving and deprecating this haste as often quite unnecessary, the patient not requiring instant service. On this occasion Fifth avenue was crowded with pedestrians and vehicles when an ambulance rushed down the street, clanging its bell and approaching a baker's wagon so closely that to avoid an accident the driver ran his horse on to the sidewalk, thus imperilling the lives of those walking down the avenue. The latter wagon had just recovered its balance enough to proceed on its way when the ambulance driver lashed his horse and plunged after the baker, and, overtaking him, settled the matter with words. It was ascertained later that the patient had sustained "laceration of the arm" and that this terrific speed was not necessary. With the multitude of vehicles of various kinds that throng many of the streets this is a serious matter and one which requires the attention of the authorities.

Tuberculosis in Prisons and Reformatories.

The subject of tuberculosis in prisons is exciting much interest The secretary of the State Board of Health of Indiana, Dr. Hurty, speaking of the Indiana State Reformatory, says: "This reformatory is in reality a prison for males, but no one over 30 years of age is confined here. In 1899 the Legislature appropriated a quarter of a million dollars to build a new cell-house, containing 600 cells. During the construction of this building it was necessary to provide for the prisoners in the old cell-house, and temporary forced ventilation was provided. A space, however, formerly intended for 200 is now crowded with almost 600, and the consequence is a rapid increase in tuberculosis. There are now not less than 200 cases of this disease, all forms of which abound. Meningitis has killed a few and general tuberculosis is very common." *Charities*, the official organ of the Charities Organisation Society of the city of New York, devoted its January number to the consideration of the prevalence of this disease in the Elmira Reformatory in New York State The board of managers of this institution report for the year ending September as follows: "For a number of years tuberculosis has been an increasing and dangerous feature among the inmates of the Elmira Reformatory. Many arrive with it, in a more or less advanced stage; others develop it under the trying conditions of prison life, with cellular confinement, association with those already affected, and all unite in communicating the subtle and poisonous infection to their clothing, their bedding, and the air of the cells and corridors." The management further became convinced, by careful scrutiny extending over many months, that prisoners, healthy upon arrival, became affected, and sometimes with astonishing rapidity, by the disease, from being steadily confined in the same cell with a tuberculous subject. Inquiry proved that thus far, as concerned this disease, no direct classification had ever been made, and that no orders existed, nor was it the practice of the authorities to exclude from the ranks of the employés such persons as came from families where this disease prevailed, or the other infectious diseases, diphtheria, scarlet fever, measles, and similar complaints. This agitation will doubtless lead to some active measures being taken to reduce this danger to its lowest possible point. Sing Sing Prison also reports cases of tuberculosis.

Compulsory Vaccination Sustained.

The Supreme Court of Pennsylvania recently rendered a decision sustaining the ruling of a lower court that an Act to make the vaccination of children a prerequisite to admission to the public schools is constitutional and valid. "We think," the opinion holds, "that the court below did not err in the ruling referred to in the assignments. In Duffield *v.* Williamsport School District we held that school directors, in the exercise of a sound discretion, may exclude from the public schools pupils who have not been vaccinated. Whether a resolution excluding from the school pupils who have not been vaccinated is a reasonable one is to be judged of in the first instance by the school directors. In the present state of medical knowledge and of convincing opinion of those having charge of the public health the courts will not say that such a resolution is an abuse of official discretion."

May 29th.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Bernese Sanatorium for Tuberculous Patients.

DR. KAESER publishes the following details with regard to the results obtained in 1899 at the Bernese Sanatorium for Consumptives at Heiligenschwendi. As regards admission he classifies the patients with respect to slight, medium, and severe affections of the lung. In discharging them he also establishes three classes. Avoiding the term "cured," he classifies those cases as "much improved" in which all rhonchi have disappeared, the cough and expectoration have ceased, and complete capability for work can be expected for a long time; as "better," cases with slight remaining non-crepitant rhonchi, but where the capability for work for a lengthened period of time seems doubtful; and, lastly, "cases not improved." The result in the 352 cases of the year he tabulates as follows. Of the slight cases 63 per cent. were much improved and 31 per cent. were improved, whereas of the cases of medium severity of the affection only 24 per cent. were much improved and 57 were improved. This proves the great desirability of patients being sent there in the first stage of consumption. The results in cases of children are exceptionally good; this coincides with Dr. Hurlimann's experiences in his private sanatorium at Aegeri in the canton of Zug. The sanatorium of Heiligenschwendi was opened in 1895 as the first sanatorium on the continent for poor tuberculous patients, and has up to now accommodated over 1600 patients The definite results from a practical point of view are very encouraging, as 70 per cent of the discharged patients were fit to resume their usual occupations.

Medical Pauperism

That the battle of life with its dire consequences, both for the public and for the medical profession, rages even in Switzerland in country districts may be gathered from an advertisement published in a local paper in which a duly qualified German lady (with a Swiss diploma) announces that she gives medical advice at her office daily from 8 to 10 A.M. and from 12 30 to 3 P.M. for the moderate charge of 5*d.*, including medicine. Charges for visits at the patient's house, including medicines, increase up to a maximum of 1*s* 8*d.*, according to the distance.

Zürich, May 31st.

SOCIETY OF MEDICAL PHONOGRAPHERS.—This society will hold its next annual shorthand examination early in May, 1902 Two prizes will be offered, each of the value of £5, one for first-year students and one for students of more than one year's standing. The competition will be open without entrance fee to any registered medical student in the United Kingdom who has not taken a first prize at one of the society's previous examinations. It will be held simultaneously in London, Edinburgh, Dublin, and at any provincial medical centre in the United Kingdom at which not fewer than three candidates shall offer themselves. Intending candidates should send in their names as early as possible to Dr. P. G. Griffith, Bonhams, Hayward's Heath, Sussex, who will furnish them in return with a detailed prospectus of the examination. The latest date for receiving entries will be April 15th, 1902.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

◆

THE seventy-first session of the General Council of Medical Education and Registration promises to be of shorter duration than some recent sessions. At any rate, members are anxious that this should be the case, and if we may judge from the experience of the first two sittings they are likely to succeed. One consideration that weighs with them is that long sessions mean heavy charges and the finances of the Council at present are not too flourishing. Another is that a considerable number of the Members wish to be free on Wednesday to attend the celebration of the ninth Jubilee of the University of Glasgow. As a matter of fact, the Council in its corporate capacity has deputed its President and Senior Treasurer to attend the celebration and to present an address of congratulation.

There are two changes in the *personnel* of the Council on this occasion, happily neither of them due to the hand of death. After a service of a quarter of a century Mr. T. Pridgin Teale has retired and in his place the Crown has nominated Sir John Williams, who may be depended on to do useful work, while Sir Dyce Duckworth has made way for Dr. Norman Moore in the representation of the Royal College of Physicians of London. Sir Dyce Duckworth will be especially missed in connexion with the work of the Examination Committee, of which important body he was for many years chairman.

Since the University of Birmingham was admitted to representation the Council has consisted of 31 members, and it is satisfactory to find that number in attendance Dr. D. C. McVail was detained in Glasgow on the first day of the session, but the second sitting saw him in his accustomed place.

A deputation appointed by the signatories to the memorial on the subject of the employment of unqualified pharmacists by medical practitioners in Glasgow and the west of Scotland was in attendance for two days but was declined a hearing. The sense of the Council seemed to be that if it received the deputation it might prejudice certain fresh cases in this connexion now before the Penal Cases Committee, and further that the statement made from the chair in the Airdrie case ought to go a long way towards allaying the apprehensions of the memorialists.

The Council is in full swing of work and though its programme is loaded with questions of much delicacy and difficulty a great attempt will be made to bring the session to a conclusion not later than Monday next. The questions which take up most of the time of the Council are questions of discipline, in which it is, of course, impossible to proceed with haste. In view of economising time it is a great point gained that the penal cases have been brought forward on the second instead of on the third day of the session and are being disposed of without any undue delay.

The case of Dr. H. W. Irvine came first before the Council on Wednesday. Unfortunately Dr. Irvine did not appear, pleading another engagement. The Council determined not to proceed with the further consideration of the case without his presence or without giving him a further opportunity of attending.

The important case of Dr. John Martin Thomson was disposed of on Wednesday. The Council came to the conclusion, on Dr. Thomson explaining that he had dismissed his unqualified assistant and entirely submitted himself to the judgment of the Council, not to proceed further in the case. The President made it very clear in his remarks that the Council in its judgment of Dr. Thomson's conduct had reference solely to the sale of scheduled poisons by unqualified assistants Many practitioners in Scotland feel strongly on this question. Perhaps they think that the Council has in its purview a more serious interference with the customs of practitioners in Scotland than is actually contemplated, and it is perhaps a pity that the Council did not see its way to receive a deputation which has actually been sent to London on the subject

---

Three cases in which dentists were charged with advertising in various ways were taken together by the Council on Wednesday afternoon. The Council accepted the facts as found and reported by the Dental Committee In this way the three cases were disposed of in less than half an hour; the persons complained of promising to abandon the practices in question. The cases are representative of a certain class of offenders, and should serve as a warning to the whole dental profession, or rather to that large section of it which is still far below the standard of a profession in their methods for attracting practice.

The improved pace of the dispatch of business is illustrated in the fact that by Wednesday evening the Council had disposed of motions referring to the application of Part II. of the Medical Act of 1886 to Italy and to the case of Malta.

TUESDAY, JUNE 4TH.

The seventy first session of the General Council of Medical Education and Registration was opened to-day in the Hall of the Council, Oxford-street, London, W. All the members were present except Dr. McVail, who wrote saying that he was detained in Glasgow but hoped to be with the Council on the next day. Sir WILLIAM TURNER, President of the Council, occupied the chair.

Introduction of New Members.

Dr. NORMAN MOORE was introduced as the representative of the Royal College of Physicians of London and Sir JOHN WILLIAMS as a Crown representative. Both gentlemen were welcomed by the President before taking their seats.

The President's Address

The PRESIDENT began his address by referring to the lamented death of Her Majesty the late Queen and recalled the fact that an address of condolence was forwarded by the Executive Committee of the General Medical Council, on behalf of the Council, to His Majesty the King. He then passed on to mention the loss which the Council had sustained by reason of two members not having sought re election. Those were Mr Thomas Pridgin Teale, a Crown member, and Sir Dyce Duckworth, appointed by the Royal College of Physicians of London. In succession to the former Sir John Williams had been appointed and in succession to the latter Dr. Norman Moore Passing to matters which had arisen during the recess the President referred to the deputation from the Council received by Mr. Walter Long, President of the Local Government Board, concerning death certification, a correspondence with the Lord Chancellor upon the subject of companies practising medicine, and an interview with Sir Richard Jebb about the Penal and Disciplinary Bill promoted by the Council. The Minister and the Lord Chancellor replied in the usual official form that the several matters would have their careful consideration and Sir Richard Jebb promised to look after the Council's Bill. The President continued:—

Early in the Parliamentary session I asked Sir Richard Jebb, who introduced last year into the House of Commons the Penal and Disciplinary Bill promoted by the Council, if he would again take charge of the measure and he kindly acceded to my request. It must, however, be obvious to all of us, from the state of Parliamentary business, that there is little, if any, probability of private members obtaining for their Bills a place in the Statute Book during the present sitting.

The Council will recollect that a year ago the Privy Council intimated that at the proper time they would be prepared to advise His Majesty to apply Part II of the Medical Act, 1886 to Italy. In March of the present year we received from the clerk to the Privy Council a letter to inform us that His Majesty in Council had ordered, directed, and declared that the second part of the Medical Act, 1886, shall be deemed to apply to the kingdom of Italy. Early in the year a communication was received from the Privy Council on the subject of the extension of Part II. of the Medical Act to Malta I brought the communication before the Executive Committee in February, who directed that it and the accompanying documents should be remitted for report to the Education Committee In consequence of a further letter from the Lord President of the Council, in which we were told that the Colonial Office were pressing His Grace for an early decision on the application of the Maltese Government, I consulted the chairman of the Business Committee, and it was arranged that I should supply the Privy Council with a copy of the draft report which had been prepared for the Education Committee. In presenting the draft report I pointed out that the Education Committee had not yet formally approved of it and that it had not been submitted to the Council The Committee will during the present Session present their report on this subject As a result of the important services rendered to the empire by our colonies in the war in South Africa, and of the War Office having been unable to accept the professional services of surgeons of high standing in Canada who had volunteered, on the ground that it was contrary to the Medical Act of 1858 to permit a surgeon with colonial qualifications to attend professionally to British troops, a Bill to remove this disqualification, entitled Medical Act (1858) Extension Bill, was introduced by General Laurie into the House of Commons and was ordered to be printed on Feb. 22nd. The Bill proposes that there shall be added to Schedule A of the Act of 1858 a paragraph to provide that the provisions of the Medical Act shall apply to a Doctor, or Bachelor, or Licentiate of Medicine, or Master in Surgery, of any university or medical school in the empire at which the education and examination are regarded by the General Medical Council as equivalent to those demanded from candidates for the diplomas of the bodies in the United Kingdom specified in that schedule. A copy of this Bill was transmitted by the Lord President at the end of February to the office for the information of the Council and for any remarks they may desire to offer.

In view of the delay which would necessarily be experienced before the Council could meet, I prepared and forwarded a memorandum on the Bill in which I pointed out that Part II. of the Medical Act, 1886, subject to the issue of an Order by the King in Council, provided a machinery for the registration of qualifications obtained in a colony or British possession which in the judgment of the General Medical Council could be recognised as furnishing a sufficient guarantee of the possession of the requisite knowledge and skill for the efficient practice of the profession, and that this privilege was dependent on the Colony granting in return privileges of practice to British registered practitioners as to His Majesty may seem just. The Medical Act Extension Bill, however, did not propose to confer such privileges of practice in the colonies on the registered practitioners of the United Kingdom, and although the memorandum by the promoter in explanation of the Bill seemed to imply that its only object was to enable colonial practitioners to be admitted to the naval, military, and civil services of the Crown the enacting clause would have put them for all purposes of practice on the same footing as those who hold qualifications from the bodies specified in Schedule A of the Act of 1858.

Various questions [illegible] to the Council by the University [illegible] ferred to committees. The ques[illegible] veen friendly societies and the medical profession would come before the meeting. The inspection and visitation of the final examinations of the Scottish and Irish corporations had been begun. The President continued —

In conclusion, gentlemen, permit me to state that on Wednesday, June 12th, an important function is to commence at the University of Glasgow—viz, the celebration of its ninth jubilee. As the function has an especial interest to the Scottish Members of Council, several of whom, as well as other Members of Council, desire to be present, and as in response to a communication from the University of Glasgow that the Council should send delegates to take part in the celebration the President and Senior Treasurer were asked by the Executive Committee to be the delegates and to present the congratulations of the Council, I would express the hope that the Council may be able to complete the business on our programme on or even earlier than Tuesday, June 11th, so that the Treasurer and I may be in Glasgow to take our place when the addresses from public bodies are being presented.

On the motion of Dr. MACALISTER, seconded by Mr. BRYANT, the President was thanked for his address.

The Business Committee.

On the motion of Dr. PAYNE, seconded by Dr. PETTIGREW, the following members were appointed to constitute the Business Committee—viz., Dr. MacAlister (chairman), Mr. Bryant, Dr. Bruce, and Sir Christopher Nixon.

Address to the King.

Mr. H. E. ALLEN, the Registrar, read the following report from the Executive Committee, viz.:—

The Executive Committee at their meeting on Feb 26th, 1901, were of opinion that as the General Council would not be in session for a considerable time, an address to His Majesty the King expressing condolence on the death of the late Queen and congratulation to His Majesty on his accession, should be at once presented by them on behalf of the General Council.

The Committee accordingly authorised the President and the Chairman of the Business Committee to prepare a suitable address, which was forwarded to the Home Office on March 14th, 1901, as follows:—

General Council of Medical Education and
Registration of the United Kingdom,
299, Oxford-street, London, W.

May it please Your Majesty.

We, the President and Members of the Executive Committee of the General Council of Medical Education and Registration of the United Kingdom, humbly tender to Your Majesty on behalf of the General Council the expression of our heartfelt condolence in the great sorrow which has befallen the Royal House through the lamented decease of Her late Most Gracious Majesty Queen Victoria. That grief is shared by all classes of Your Majesty's subjects, but by none more deeply than by the members of the profession of medicine to which we belong, and with whose highest interests we have the honour to be charged. We recall with profound thankfulness to the Almighty that during the beneficent reign and under the fostering care of Her late Majesty the art and science of medicine have made unprecedented advances, which have borne inestimable fruit in the amelioration of the public health and the safeguarding of human life And we gratefully cherish the remembrance that by many gracious acts of Royal favour our late beloved Sovereign manifested her enlightened interest in and appreciation of the efforts put forth by our profession for the promotion of the welfare of her subjects.

We desire, moreover, in all respectful loyalty and duty to give utterance to the unfeigned satisfaction with which we hail Your Majesty's happy accession to the Throne of these realms. We rejoice to know that Your Majesty has in the past been pleased to honour the profession of medicine by assuming a personal connexion with more than one of the ancient corporations which are represented in our Council, and that Your Majesty has ever evinced a wise and effectual interest in all that concerns Your people's health.

We pray that it may please Divine Providence long to preserve to the Empire Your Majesty and Your Gracious and beloved Consort, and to grant to Your Majesty's reign the blessings of peace, prosperity, and progress in the arts that conduce to the elevation of the national life.

We have, Sire, the honour to be,
Your Majesty's most dutiful and loyal subjects,
For the Executive Committee of the General Council of Medical Education and Registration,
WM. TURNER, President.
DYCE DUCKWORTH, } Treasurers.
THOMAS BRYANT, }
DONALD MACALISTER,
Chairman of the Business Committee.

The receipt of this address was acknowledged on April 2nd, 1901, as follows:—

Home Office, Whitehall, April 2nd, 1901.

SIR,—I am commanded by the King to convey to you hereby His Majesty's thanks for the loyal and dutiful address of the President and Members of the Executive Committee of the General Council of Medical Education and Registration of the United Kingdom expressing sympathy on the occasion of the lamented death of Her late Majesty Queen Victoria, and congratulation on His Majesty's accession to the throne.

I am, Sir, your obedient servant,
CHAS. T RITCHIE.

The Registrar, General Council of
Medical Education and Registration.

The Council adopted the report.

The University of Glasgow and its Jubilee.

The Council adopted the following report of the Executive Committee—viz.:—

The Executive Committee recommend that the following address to the University of Glasgow, in connexion with the celebration of the four hundred and fiftieth year of its foundation be adopted by the Council and presented by the President and Treasurer —

We, the President and Members of the General Council of Medical Education and Registration of the United Kingdom, present our hearty congratulations to the University of Glasgow upon the celebration of the four hundred and fiftieth anniversary of its foundation.

The University and the General Medical Council have for more than 40 years been closely associated in the common purpose of improving medical education and of raising the standard of medical examination. Empowered by statute to elect a representative on the Council the University [illegible] taken a dire[illegible] bodies in t[illegible] curriculum shall be full and adequate

The Medical Council rejoices to see that the University of Glasgow, though crowned with the venerable dignity of age, retains the freshness and vigour of youth, and it expresses the earnest hope that the services rendered by the University in times past to the advancement of literature, philosophy, science, and medicine may be continued and maintained throughout succeeding centuries.

Sir WILLIAM GAIRDNER said that he was quite sure that the University of Glasgow would receive an address so excellently worded as this with very great pleasure.

Results of Examinations.

The REGISTRAR presented a series of tables showing for 1900 the results of professional medical examinations, of examinations for diplomas in public health, of dental examinations, and of preliminary examinations, also the results of competitions in February, 1901, for commissions in the medical staffs of the navy and the army. The table with regard to professional medical examinations showed that during 1900 there were for the first examination 1307 rejections and 1628 passes, for the second examination 1234 rejections and 1918 passes, and for the final examination 1318 rejections and 2415 passes. The table with regard to public health examinations showed that during the year there were for the first examination 43 rejections and 107 passes, and for the second and final examination 16 rejections and 107 passes.

Mr. VICTOR HORSLEY called attention to a table headed "Table showing the number of exceptional cases that occurred during the year 1900 in regard to length of course of professional study, together with a statement of the action taken thereon by the several licensing bodies." This table, as he explained, was a perfect blank, and he did not think that it should be entered on their minutes. He moved to this effect.

The motion was rejected by the Council.

Dr. BRUCE moved that the whole of the tables be referred to the Examination Committee for their consideration.

Sir HUGH BEEVOR seconded this motion, saying that in his opinion the tables should always be submitted to the Examination Committee before being presented to the Council.

Mr. BRYANT said that these tables were sent for the information of the Council, and no doubt in course of time a review of them might be of value and enable them to draw deductions. But to consider each table as it was presented would, in his opinion, be an utter waste of time He suggested that the members who were interested in the tables should give them their personal attention and extract from them material which could be presented to the Council,

The motion of Dr. Bruce was rejected by 14 to 18 votes.

West of Scotland Practitioners and the Sale of Drugs and Poisons.

The REGISTRAR presented the following report from the Executive Committee, viz.:—

The Executive Committee have, in accordance with Standing Order VII, 16, examined a memorial from certain medical practitioners of Glasgow and the West of Scotland. It contains arguments of a general kind bearing upon a particular adjourned case now before the Council, and does not purport to convey further facts and evidence relevant to the present stage of these judicial proceedings. The Committee after consultation with the legal advisers are of opinion that the memorial should not in the present circumstances be received by the Council.

The particular case referred to is that of Dr. John Martin Thomson, of Clarkston, Airdrie, who in December, 1900, was charged, "That he being a registered medical practitioner habitually employs as assistants for the sale of drugs and poisons persons who are not qualified to act as chemists or pharmaceutical assistants and thereby causes such persons to commit breaches of the Pharmacy Acts." In December the Council found that this charge had been proved and adjourned the further consideration of the case until the present session.

Dr. MACALISTER moved that the report be received, entered on the minutes, and approved by the Council. The memorial, he said, was in the nature of a petition and was signed by a large number of persons, and it fell to the Executive Committee to examine it and to advise the Council upon it The Committee were warned that it was not in any sense desirable that the memorial which dealt with the general question should be taken up by the Council until the particular case had been settled.

Dr HERON WATSON seconded the motion.

[illegible] said that while he bowed to the opinion of the [illegible] w he [illegible] pro- [illegible] uncil [illegible] tion. The Council was taking a course which probably it would regret

Mr. BROWN said that the memorial was of considerable importance and should not be thrown aside. When the particular case was before the Council last session he asked the legal advisers whether it did not raise a new point.

The PRESIDENT, interrupting Mr Brown, said that he could not argue the case on the present occasion. All that was before the Council now was whether or not they should receive this memorial and a deputation.

Mr. BROWN explained that his feeling was that they should first deal with the particular case and that thereafter they would be in a position to say whether they should receive the deputation. He hoped the Council would not put the memorial aside.

Dr. MACALISTER said that all that the Executive Committee recommended was that the memorial should not, in the present circumstances, be received.

Dr. GLOVER said that apart from the particular case there were rights and duties of medical practitioners at issue [illegible] wished to present a case to this Council. Whether he agreed or not with their case was another matter, but he wished to hear the case stated. These petitioners were quite within their right in approaching the Council and asking to be allowed to present their views upon a general principle, and it appeared to him that the motion now moved was practically saying to them that the Council would not listen to them.

Dr. HERON WATSON said that the motion was a mere carrying out of the standing orders of the Council. The memorial was not competent just now because the particular case was *sub judice*. Whenever this case was finished the matter entered upon an entirely new phase.

Sir CHRISTOPHER NIXON expressed the view that it would be a singularly inopportune time for the Council to take into consideration the memorial immediately after deciding the particular case. The practitioner who appeared before them in the particular case would [illegible] have the opp[illegible] sentative, to [illegible] in this memo[illegible] all these arguments the Council would come to its decision.

The motion of Dr MACALISTER was carried by a large majority.

Medical Aid Associations.

On the motion of Dr. MACALISTER, seconded by Dr. GLOVER, it was resolved to receive and to enter on the minutes the following communication (remitted to the General Council by the Executive Committee) from the British Medical Association in regard to the question of a proposed Conciliation Board:—

British Medical Association, General Secretary's Office,
429, Strand, London, W C, May 20th, 1901.

DEAR SIR,—At a meeting of the Council held on the 17th ult. a resolution was passed upon the report of the committee appointed to confer with the friendly societies upon the question of a proposed Conciliation Board.

I shall be glad to hear from you when it will be convenient for the General Medical Council to receive a deputation.

I am, yours faithfully,
FRANCIS FOWKE, General Secretary.
The Registrar, General Medical Council.

The resolution referred to in the foregoing letter is as follows:—

That this Council reports to the General Medical Council the result of their conference with the friendly societies and asks that the General Medical Council receive a deputation.

Dr. MACALISTER next moved—

That the Medical Aid Associations Committee be empowered to receive on behalf of the Council a deputation from the Council of the British Medical Association on the subject referred to in the general secretary's letter of the 20th May, 1901, and that the Committee report, if possible, during the present session the results of its interview with the deputation.

Dr. BRUCE seconded this proposal.

Mr. BROWN thought that a deputation from the British Medical Association should be received by the Council itself rather than by one of its committees.

Dr. MACALISTER explained that the motion made it clear that the deputation would be received on behalf of the Council. On at least two previous occasions a similar course had been adopted.

Mr. BROWN did not think that, as a rule, deputations should be handed over to committees In this case the British Medical Association had asked the General Medical Council to receive them and he thought that as a matter of courtesy they ought to have done so, afterwards referring their memorial to a committee if necessary.

The PRESIDENT: But these gentlemen have not presented any memorial.

Mr. BROWN contended that in cases where his professional brethren were anxious to instruct him as a member of the General Council he did not think it was right that the Council should relegate the hearing of what they had to say to a committee.

Dr GLOVER said that as chairman of the Medical Aid Associations Committee he entirely sympathised with Mr. Brown in the feeling he had given expression to At the same time he saw difficulty in the way of deputations being received by the General Council, especially because of the present state of the Council's finances. If every question of interest to the profession was to be discussed before the Council the expenditure would be very much increased instead of being reduced. He believed that the object which the British Medical Association had in view would be duly secured by the course which it was now proposed to adopt.

Mr. HORSLEY believed that the course suggested would commend itself to the Council of the British Medical Association.

The motion was then agreed to.

Opinions of Counsel.

The Council sat *in camerâ* to receive a report from the President on the subject of the opinions of counsel. On the re-admission of the public no announcement was made as to any decision.

Reciprocity of Practice.

The REGISTRAR read the following report by the Executive Committee in regard to the extension of Part II. of the Medical Act, 1886, to Italy:—

The Committee has to report that at its meeting on June 3rd, 1901, it received from the Privy Council Office the following Order in Council, dated March 9th, 1901:—

[illegible] Part II. of the Medical Act, 1886, to Italy.

I am, Sir, your obedient servant,
The Registrar, General Medical Council. A. W. FITZROY.

AT THE COURT OF ST. JAMES'S,
The 9th day of March, 1901.
Present The King's Most Excellent Majesty.

Lord President, Earl of Derby, Earl of Kintore, Earl of Ducie, Earl Roberts, Viscount Peel, Lord Wenlock, Lord Tweedmouth, Lord James of Hereford, Lord Heneage, Sir James Fergusson, Bart., Sir Francis [illegible] is provided (amongst other [illegible] to time, by Order in Council, [illegible] Act shall be deemed [illegible] after a day to be [illegible] which, in His Ma[illegible] the United King[illegible] country as to His [illegible] named in such [illegible] to be a foreign [illegible] meaning of the [illegible] and that until such Order in Council has been made in respect of any foreign country the said second part of the said Act shall not be deemed to apply to any such country.

And where[illegible] to the regist[illegible] privileges of [illegible]

Now, ther[illegible] of His Privy [illegible] the Medical [illegible] Italy.

A. W. FITZROY.

The committee considered [illegible] Agostin[illegible] registra[illegible] It was [illegible] Italian [illegible] siderati[illegible]

Mr. HORSLEY asked the President whether he had any information in respect to the Bill promoted in the Italian Parliament to exclude practitioners of foreign countries not granting reciprocity from practising in Italy. A year ago the Council had been informed that the English practitioners in Italy were of opinion that the Privy Council should not take action in this matter until the Bill in question had passed into law.

The PRESIDENT said he had no information upon the subject.

Mr. TOMES said his information was that up to last month no measure of the character referred to had been passed by the Italian Parliament, nor did it seem likely that any Act of the kind would be passed. Consequently the action of our Privy Council had been taken under the old Act, which had reference alone to practitioners practising amongst the foreign community in Italy and prohibited from attending Italians

Mr. HORSLEY said that, as usual, the General Medical Council had been entirely given away in this matter by the Privy Council. It had been recently stated in the House of Commons that the Privy Council did not read the minutes of the General Medical Council, and that being so, he could quite understand their action. It was of no use for the General Medical Council to make representations to the Privy Council as to what was the actual state of affairs, because the Privy Council took no interest in the matter. He thought that this should be made known publicly, so that it should be seen how they had been thrust into their present position by the action of the Privy Council.

Further discussion on the subject was adjourned.

Society of Apothecaries of London.

On the motion of Sir HUGH BEEVOR, seconded by Mr. BRYANT, it was agreed that Mr. William Bruce Clarke, F.R.C.S. Eng., M.A., M.B Oxon., assistant surgeon to St. Bartholomew's Hospital, be appointed an assistant examiner in surgery to the Society of Apothecaries of London for a term of four years, in the room of Mr. C. B. Lockwood, F.R.C.S. Eng., who is retiring from office by rotation.

Exemptions from Examinations.

Dr. MACALISTER moved that the following report by the Registrar on the exemptions granted by the licensing authorities during the years 1897, 1898, and 1899 be entered on the minutes:—

I. Report—1. On Dec. 4th, 1900, the General Council passed the following resolution: That the medical authorities who grant exemptions in any part of the examinations which they hold be requested to furnish the Council with a detailed list of the exemptions granted by them in the examinations held during 1897, 1898, and 1899. 2. The medical authorities were made acquainted with this request on Dec. 13th, 1900, and have supplied the desired information. 3 The Registrar, having made a summary of the answers, submitted it on Feb. 25th, 1901, to the Executive Committee when it was directed that the replies by the several authorities should be printed *in extenso* for the information of the General Council.

II. Summary—The English Conjoint Board sends detailed lists showing that, during the three specified years 461 persons were exempted from both the first and second examinations; that the exemptions granted from the entire first examination were 269, and from chemistry alone 46, and biology alone 38. All these exemptions were granted on the ground that the candidates were students from British, Colonial, Indian, or foreign universities.

The Royal College of Physicians of London states that as regards its separate licence one candidate from the University of London was exempted in 1897 from chemistry only, and that in 1898 two students from Dalhousie [College and University], Halifax, and Bombay respectively were exempted from the first and second examinations. In 1899 no exemption was granted.

The Royal College of Surgeons of England states that exemptions from examination under the old regulations have been granted during the three years to eight candidates from various universities.

The Apothecaries' Society of London states that no exemptions whatever are granted from any part of the final examination. During the three years 320 candidates were exempted from one or more of the subjects of the primary examination on the strength of having satisfied the examiners either at British medical corporations or British, Canadian, Indian, or foreign universities; one candidate, however, being exempt on the ground of having passed an examination of the Pharmaceutical Society of Great Britain.

The University of Durham sends a list of 42 exemptions granted during the period from certain subjects on the ground of their having been already passed before other licensing bodies except in one case where the candidate was a B.Sc. of the University. No exemptions will be allowed after September, 1901.

The Victoria University sends details of five persons exempted, one of whom was admitted to the final and four exempted from certain subjects in the first M.B. examination. Four were students of other universities; one did not avail himself of his exemption.

The Scottish Conjoint Board states that during the three years 24 candidates were exempted from portions of the first examination, 60 were exempted from certain subjects in the second examination, 19 from certain subjects in the third examination, and 180 were exempted altogether from the first and second, or first, second, and third examinations, on the ground of having passed examinations embracing such subjects of other British, colonial, or foreign licensing authorities. The Royal College of Physicians of Edinburgh and the Royal College of Surgeons of Edinburgh state that they have nothing to add to the lists supplied by the secretary of the Conjoint Board. The Faculty of Physicians and Surgeons of Glasgow states that the faculty, acting apart from the Conjoint Board, has not granted any exemption from examination.

The University of Edinburgh only grants exemptions in the subjects of the First Professional Examination—viz., botany, chemistry, physics, and zoology, and that only to candidates who (*a*) have completed, in a University of the United Kingdom, a course of study, and have passed an examination in one or more of these subjects, qualifying for a degree in Science or in Arts; or (*b*) have obtained a degree in Science or in Arts in any foreign or colonial university recognised for the purpose by the University Court, granted in either case after having completed a course of study and passed an examination in one or more of these subjects. During the three years specified in the resolution of the General Medical Council—viz, 1897, 1898, and 1899—28 exemptions were allowed to candidates coming from the Universities, in the United Kingdom, of Aberdeen, St. Andrews, Glasgow, Cambridge, Victoria, Royal University, or from the Universities of Madras and New Zealand.

The University of Aberdeen reports one case in 1897, where the candidate was exempted from botany, zoology, and chemistry on the ground of having taken the subjects at Edinburgh University for the Bachelor of Science degree.

The Irish Conjoint Board sends particulars as to eight candidates who were exempted during the three years from certain parts of the professional examination on the ground of having passed similar examinations; in six cases at the old Conjoint Board of the Royal College of Surgeons and the Apothecaries' Hall, Ireland; in one at the Royal College of Surgeons in Ireland under the old scheme; and in one at Bombay University. No exemptions are granted in any part of the final examination. The Royal College of Physicians of Ireland had no exemptions except that registered practitioners of five years' standing were exempted from printed questions when offering themselves for the licence in midwifery. The Royal College of Surgeons in Ireland states that it has nothing to add to the communication sent by the Secretary of the Conjoint Board in Ireland. The University of Dublin states that four candidates were examined, to whom certain exemptions had been granted, and that three passed. The Apothecaries' Hall, Dublin, states that during the three years four candidates, who commenced study before 1892, were exempted from special examination in ophthalmology and biology. Also one graduate of the New York State University, who had also studied in Dublin for two years, was specially exempted, being admitted to examination in Pathology, Hygiene, Forensic Medicine, and all the final subjects.

The following have not granted any exemptions: the University of Oxford, the University of Cambridge, the University of London, the University of Glasgow, the University of St. Andrews, and the Royal University of Ireland.

Mr. HORSLEY, in seconding Dr. MacAlister's motion, said that the foregoing report was a most important one, as it laid before the Council for the first time what were the actual facts. Hitherto, instead of the actual facts the Council had had given to them the misleading "Table E" All that Dr. MacAlister asked for by his motion was that while the false return appeared on the minutes the true return should also appear.

Dr. MACALISTER said that while the return was Mr. Horsley's the interpretation which Mr. Horsley put upon his motion was one which he could not accept. In both cases the tables were true. The information tabulated depended upon the question put.

Mr. HORSLEY wished to know what was the question put to the licensing authorities for the construction of "Table E."

Dr. MACALISTER asked Mr. Horsley if he proposed to put forward any specific motion on the subject.

Mr. HORSLEY: Oh, no; I shall be content to get this report on the minutes to-day, and next session we may get rid of "Table E."

The motion was agreed to.

Praise from the President.

The PRESIDENT congratulated the Council on having got through more business than he had ever previously seen disposed of in so short a time as an hour and three quarters.

The Council adjourned.

WEDNESDAY, JUNE 5TH.

The Council met again to-day when all the members were present, Sir William Turner, the President, being in the chair.

The Case of Dr. Henry Ward Irvine.

The Council proceeded to the consideration of the adjourned case of Dr. Henry Ward Irvine of Cornwall-buildings, Newhall-street, Birmingham, registered as M.B., Bac. Surg., 1895, M.D. 1897, Univ. Dub.

When the case was called it was found that Dr. Irvine was not present. Dr. Bateman attended to watch the case on behalf of the Medical Defence Union.

Mr. WINTERBOTHAM, solicitor to the Council, explained the circumstances of the case. The charge made against Dr. Irvine at the last session was—

That he accepted the office of consulting physician to the Consultative Medical and Surgical Institution, Birmingham, at a salary, and approved or acquiesced in the extensive advertisements issued by that institution by posters exhibited in the various manufactories, trading establishments, and mercantile offices of the city, by advertise- [illegible]

The complainant in the case was Dr. Robert Saundby of Birmingham. On Nov. 29th, 1900, at the conclusion of the deliberation of the Council on the case, the President informed Dr. Irvine that the charge which he had been required to answer had been proved to the satisfaction of the Council; that the further consideration of the charge proved against him had been adjourned until the May session; that the Council regarded the conduct complained of as being of a serious character; and that in adjourning the case it gave him an opportunity to reconsider his position. In accordance with the standing order it became his duty to serve formal notice upon Dr. Irvine that the case would come up to-day. That notice was served on April 30th and a similar notice was sent to the complainant The following letter was received from Dr. Irvine by the Registrar. It was not dated, but he believed it was sent on April 4th; at any rate, it was before the date of the notice to appear at the meeting. The letter was in these terms, viz.:—

The Registrar General, Medical Council.

Birmingham, April, 1901,

DEAR SIR,—I shall be glad if you will inform the General Medical [illegible]

HENRY WARD IRVINE.

Two days ago he (Mr. Winterbotham) received the following letter, viz.:—

47, Upper Belgrave-road, Clifton, June 3rd, 1901

DEAR SIR,—You will recollect the correspondence that has already passed between us with reference to [illegible] the General Medical Council on the 5t[illegible] correspondence between myself and [illegible] also within your knowledge. I have [illegible] possible to attend the meeting and g[illegible] that my connexion with the Instit[illegible] which they expressed disapproval had entirely ceased, but I find that urgent business will now prevent me going to London on that day This I very much regret. I regret also that the person who had undertaken to represent or advise me before the Council has now withdrawn his promise to do so, and I have only to-day received his intimation to that effect. At such short notice you will see that I cannot possibly obtain the services of a competent representative. But since the Council will feel assured from my correspondence with yourself and the Registrar of the Council that the announcements regarded by the Council as advertisements (which evidently were the object of the Council's disapproval) were withdrawn immediately after the C[illegible] had expressed its disapproval [illegible] Birmingham Institution has [illegible] that the Council will accept [illegible] will have noted that I have a[illegible] to the Registrar of the Coun[illegible] received any notice from you [illegible]

I [illegible]

H. W. IRVINE.

P S.—I am informed by Dr. Saundby that he does not propose to offer any additional evidence.

Yesterday he sent a telegram to Dr. Irvine in these terms, viz.:—

To Dr. Irvine, 47, Upper Belgrave-road, Clifton, Bristol.

The Council have no power to compel your attendance, but I strongly urge you to attend personally, and if this is impossible to explain fully the nature of the engagement which prevents you from attending, and if you are not personally present you should instruct a solicitor or counsel to appear for you. In my judgment you will do most unwisely to fail to appear on the summons.

From WINTERBOTHAM.

To this telegram Dr. Irvine had replied in a letter marked "personal and private" in which he said that his engagements in the public service made it impossible for him to come to London.

Dr. BATEMAN intimated on behalf of the complainant that he had no further evidence to offer and that he left the case in the hands of the Council.

The Council then sat in private for about three-quarters of an hour.

The PRESIDENT, when strangers were re-admitted, announced the following resolution:—

That the Council does not think fit to proceed this day with the final stage of this inquiry in the absence of Dr. Irvine; determines to postpone the consideration of the case till Saturday next at 1 P.M.; and instructs the solicitor to require Dr. Irvine to attend here on that occasion when the case will be disposed of.

The Case of Dr. William Allen.

The Council then took the case of Dr. William Allen, of Shotley Bridge, County Durham, registered as M.D., Mast. Surg. 1877, Queen's University, Ireland, which had been adjourned from last session. The charge found proved against Dr. Allen was:—

That, being a registered medical practitioner, he on two occasions gave and signed certificates of deaths of persons on whom he had not [illegible] had been to his knowledge [illegible] ualified person named Burke, [illegible] nd treating patients, and [illegible] a duly qualified medical practitioner.

Dr. Allen attended accompanied by a legal representative. The latter read a number of affidavits with regard to Dr. Allen's methods of conducting the practice since the proceedings in December last, and on behalf of Dr. Allen expressed regret for what had taken place and gave an assurance that in the future he would scrupulously observe all the regulations of the Council.

After a short deliberation in private the PRESIDENT announced to Dr. Allen that the Council, having considered further the charge, did not judge him guilty of "infamous conduct in a professional respect." The case, therefore, was at an end.

The Case of Dr. J. Martin Thomson.

The Council proceeded with the consideration of the case of John Martin Thomson, of Clarkston, Airdrie, Scotland, registered as M B, Mast. Surg. 1891, Univ. Edin.

Mr. WINTERBOTHAM explained that this case was originally considered on Dec 3rd last. The charge made against Dr. Thomson then was—

That he, being a registered medical practitioner, habitually employs as assistants for the sale of drugs and poisons persons who are not qualified to act as chemists or pharmaceutical assistants, and thereby causes such persons to commit breaches of the Pharmacy Acts.

The complainants, the Pharmaceutical Society, were represented, as they now were, by Mr. Peter Morison, jun., S.S.C., Edinburgh, solicitor to the society, and Mr. John Rutherford Hill, Edinburgh, assistant secretary to the society, while Dr. Martin Thomson was represented by his counsel, Mr. T. E. Saunt, instructed by Messrs. Blyth, Dutton, and Co, solicitors, Gresham House, London. Evidence had been given, and the Council came to the following decision:—

(*a*) That the charge made against Mr. John Martin Thomson had been proved to the satisfaction of the Council (*b*) That the further consideration of the charge proved against Mr. John Martin Thomson be adjourned till the next session of the Council.

Due notice of the date of the adjourned consideration of the case had, on April 30th last, been sent to both Dr. Thomson and the complainants, but neither had intimated to him (Mr. Winterbotham) that it was intended to submit fresh facts or new evidence

Mr. SAUNT said that all he had to submit was that previously to being brought before the Council last year Dr. Thomson had not known that he was heinously offending, but so soon as the Council gave decision on the charge made against him he went home and set his house in order. He had at once secured a qualified assistant and he was desirous of submitting himself to the wishes of the Council.

Dr. THOMSON, in examination by Mr. SAUNT, bore out this explanation He had, he said, immediately after the trial of his case last year secured a qualified dispenser who was with him still. He had no connexion whatever with any persons who had approached the General Medical Council on the subject of the attendance of assistants in doctors' shops in the west of Scotland and he had nothing whatever to do with the memorial which had been presented to the Council. He desired to submit himself to the General Medical Council and to be guided by them in every respect.

Mr. MORISON said that he had no questions to ask. The Pharmaceutical Society were now prepared to admit that Dr.

Thomson had employed a qualified assistant in his shop since Dec. 3rd last, and that the society had had *no complaints* since the last meeting of the Council.

As no member put any question, the Council proceeded to consider their decision *in camerâ*. On the re-admission of the public,

The PRESIDENT, addressing Dr. Thomson, said: The Council has come to a resolution which I shall read to you. The Council, having further considered the charge proved against you, does not judge you guilty of "infamous conduct in a professional respect." But in connexion with this decision to which we have come the Council thinks that I ought to say one or two words in addition. It has been proved to the satisfaction of the Council that you, being a registered practitioner, have repeatedly permitted your unqualified assistants, for your profit, illegally to sell scheduled poisons to the public. You have thereby, under cover of your professional qualifications as a registered medical practitioner, enabled such assistants to commit breaches of the law for which they have been punished. Other lamentable consequences have also resulted, to which I need not further refer now. The offence proved against you is grave and fraught with danger to the public, but in view of the fact that your case is the first of the kind which has been brought before the Council, and in view of your assurance that you will in future carefully avoid any similar grounds of complaint, the Council has decided to deal leniently with you and will not proceed further in relation to the charge

Unqualified Pharmaceutical Assistants.

Mr. BROWN thought that seeing that they had now disposed of Dr. Thomson's case they should agree to hear the representatives of the west of Scotland practitioners who had sent to them a memorial on the subject. Certain gentlemen from Glasgow were waiting in London, and although he was quite sure that they would receive the Council's decision in the Thomson case with all respect, yet as representing a large body of practitioners he thought that they ought to be heard.

Dr. BRUCE and Dr. MCVAIL were of the same opinion The former pointed out that if the deputation were received they would not occupy much of the time of the Council, because he was informed that no more than two gentlemen would offer to present the case

The PRESIDENT said that he had hoped that the deliverance in Dr. Thomson's case, which had been drafted with great care, was of such a nature as would do away with the need of having the deputation from Scotland.

Dr. GLOVER thought that if this deputation was to be heard at all they should be received, not by the Council, but by one of its committees These west of Scotland memorialists might be dealt with in the same way as the deputation from the Council of the British Medical Association, who were to be heard through a committee. Any interview that they might have on the subject of their memorial should take place during the hours not occupied by the sitting of the General Medical Council.

The PRESIDENT: What I would suggest is this—that after reading our deliverance these west of Scotland representatives may feel that their doubts and difficulties have been removed, and that therefore there is no need for them to plead any point raised in their memorial.

Mr. BROWN was not satisfied. There was, he asserted, no special committee in existence that could deal with the matter, and there was no committee of Council that could deal with it so well as the Council itself.

The PRESIDENT asked liberty to give what he called a piece of information. The Council, he said, could not consider that in disposing of Dr. Thomson's case they had disposed of the whole question involved, because the Council—perhaps he might say its Executive Committee—knew that there were other cases similar to Dr. Thomson's pending. These cases had not come before the Council yet, and the question therefore arose whether by hearing the west of Scotland memorialists they would not put themselves into a somewhat difficult position as regarded these additional cases that they might have to hear. That was a view which the Council could not lose sight of. He hoped that Mr. Brown thoroughly understood that the Council had no wish to put the memorialists into a wrong position in this case The Council entirely respected their position, but again he must urge that what he had said in the Thomson case should be sufficient to allay their apprehensions.

SIR CHRISTOPHER NIXON was opposed altogether to any hearing being granted to the deputation. These gentlemen had had the opportunity of putting forward their views in their memorial, and if they were to be heard it would simply be a reopening of the Thomson case which the Council had just decided.

Dr. MCVAIL wished to point out to his friend that if the deputation were received and if they harked back on the Thomson case or said anything improper it was in the power of the President to stop them.

Dr. LITTLE did not think that there should be any hesitation in refusing to hear this deputation. They and the subject that they wished to speak upon were of much less importance than the British Medical Association and their subject of a Conciliation Board which had been referred to a committee of the Council.

Dr LOMBE ATTHILL strongly opposed the reception of the deputation at all. If there was anything in their memorial it was a request to the Council to wink at an existing practice which tended to infringement of the law of the land. He was prepared to treat the memorial with every respect, but seeing that there were similar questions pending he did think that the deputation would be a most improper one for them to receive.

After a remark by the PRESIDENT that it would be a serious matter for the General Medical Council if they were to allow themselves to be influenced by outside parties in the conduct of their judicial duties,

Mr. HORSLEY stated that he could not vote for the reception of the deputation by either the Council or one of its committees. His opinion was that, however guarded language they might use, any deputation could not avoid trenching on judicial matters. Under present circumstances he thought that the deputation ought not to be allowed.

The PRESIDENT demanded a formulation of the motion and amendment.

Dr. GLOVER submitted his amendment in the following terms:—

> That the Executive Committee of the General Medical Council be empowered to receive the memorialists from the west of Scotland on the subject of the sale of scheduled poisons by unqualified assistants employed by general practitioners on Friday, at 12 o'clock.

On a vote this proposal was rejected, as only four members of the Council supported it.

Mr. Brown's motion was then put. Its terms were these:—

> That the memorialists in regard to the employment of unqualified dispensers in Scotland be permitted to appear before the General Medical Council by deputation on Friday next.

On a division 20 members voted against this motion, eight voted for it, two did not vote, and one member was declared to be absent.

As both amendment and motion were rejected, nothing more can be heard of the Scotch case during the present session

The Case of Nottingham Dentists.

On the Dental Committee's report on the cases of Messrs. Isaac Jeffries Dadley, Henry Smith Clarke, and Reuben Widdowson being reached,

The PRESIDENT, as chairman of the Dental Committee, stated that all these three gentlemen were in practice in the town of Nottingham, and they were all charged with practically the same offence—namely, advertising in an objectionable way. When the matter came up before the Dental Committee all the accused had consented to their cases being taken together. Perhaps the same course could be followed in the Council. If there was no objection he would call upon the three persons who had been summoned.

The suggestion was agreed to, and there appeared thereupon Dr. Hugh Woods, secretary of the London and Counties Medical Protection Society, Limited, the complainants; Mr. Dadley, accompanied by Mr Ockerby, his solicitor; Mr. Wright-Motson, on behalf of his client, Mr. H. Smith Clarke; and Mr. Widdowson for himself.

The REGISTRAR read the reports of the Dental Committee which were—

> In the case of Mr. Dadley the committee find that the following facts were established by the evidence—(a) That Isaac Jeffries Dadley was registered in the Dentists' Register as in practice before July 22nd, 1878, and his address in the *Dentists' Register* is 19, *Carter-gate, Nottingham* (b) That Isaac Jeffries Dadley has habitually issued and caused to be issued advertisements in various magazines and newspapers and local theatre and music hall programmes and tramway tickets and has exhibited in the Great Northern railway station at Nottingham a show case containing artificial teeth and a photograph of himself with his name, description, and address in large letters. (c) The said I. J. Dadley has withdrawn all the advertisements

complained of and undertakes not to advertise in future anything beyond his name and address, and further to abide by any expression of the views of the Council on the subject of advertising in general The evidence before the Committee consisted of: (a) A statutory declaration of Dr Hugh Woods dated Sept. 23th, 1900, (b) various advertisements [illegible] that declaration (c) a letter [illegible] ing [illegible] ith [illegible] ice [illegible] ter is 1, Clarendon-street, Nottingham (b) That Henry Smith Clarke has habitually issued and caused to be issued advertisements in various parish magazines, on various cards of the Notts County Cricket Club and of the Notts Forest Football League, and in a pamphlet and leaflet issued by him (c) Mr Clarke's solicitor stated on his behalf that Mr Clarke had taken steps to withdraw all the advertisements complained of, and undertook for the future to discontinue the issue of advertisements of any kind The evidence before the committee consisted of: (a) A statutory declaration of Dr Hugh Woods, dated [illegible]

[illegible] Reuben Widdowson was registered in the Dentists Register as in practice before July 22nd 1878, and his address in the Dentists Register is 12, Arkwright-street, Nottingham. (b) That Reuben Widdowson has habitually issued and caused to be issued, advertisements in railway time-tables and in a parish magazine; and he also [illegible] and undertakes not to advertise [illegible] and address and further to abide [illegible] Council on the subject of advertis[illegible] the Committee consisted of: (a) A statutory declaration of Dr Hugh Woods, dated Sept. 23th, 1900, (b) various advertisements and a photograph exhibited to that declaration, (c) a letter from Mr Widdowson to the solicitor to the Council dated Jan 25th, 1901.

Having by standing orders the option to either hear parties or to consider forthwith the Dental Committee's reports, the Council agreed to do the latter, and the room was cleared On the re admission of the public,

The PRESIDENT intimated that the resolution come to as respected each of the three cases was this —

> That the Council, taking note of your withdrawal of the objectionable advertisements complained of and of your assurance that you will abstain from the issue of like advertisements in future has decided to proceed no further in reference to the facts proved against you.

Reciprocity for Malta

Sir JOHN BATTY TUKE, on behalf of the Education Committee, submitted a report on the recognition of the medical degrees of the University of Malta The question, he said, had been raised by the receipt of the following communication from the Privy Council Office —

> [illegible]
>
> It will be observed that the immediate cause of this action of the Maltese authorities was a rumour that it was proposed to extend Part II of the Act to Italy As the Medical Council are doubtless aware, the attitude of the legislature of Italy, as recently reported by THE LANCET, towards the question of the practice of medicine by English practitioners in that country renders doubtful the possibility of the application of Part II to Italy in the near future
>
> The Lords of the Council, however, propose to consider the present application from Malta on its merits, irrespective of any arrangements with Italy
>
> As regards the amendment in the Draft Ordinance proposed by the Crown Advocate in his letter of the 25th of September last I am to state that the Secretary of State is disposed to think that it might be better to omit the whole of the third paragraph of Section 5.
>
> The Lords of the Council would be glad to be furnished with any information at the disposal of the General Medical Council as to the status of the Diplomas of the University of Malta, having regard to Section 13 (1) of the Medical Act, 1886.
>
> I am Sir, your obedient servant,
>
> A. W. FITZ ROY

The Education Committee, Sir John Batty Tuke said, had very carefully considered this letter and all the documents referred to in it and had framed a series of three resolutions on the subject which he now wished the Council to adopt

Dr MCVAIL objected that the matter was too important to be pressed forward so hastily He had not had time to thoroughly examine this report and he wished for adequate time If the Council adopted its recommendations now they would practically be allowing the Education Committee to act for them If the report was gone on with now it would be simply a case of "Shut your eyes and open your mouth and see what you will get"

Mr. HORSLEY said that he had received a copy of the report only that morning He, however, had read the documents it contained during the day, and he should certainly vote for the Education Committee's report

The recommendations, on the motion of Sir JOHN BATTY TUKE, seconded by Dr MACALISTER, were then adopted as follows —

> 1 The regulations abstracted in Section 3 (pp 15-26) indicate that [illegible] Malta are granted after a [illegible] over four years following [illegible] xtending over three years The two courses, in combination appear to the Committee to be not [illegible] takes place the fourth condition contained in Section 5 of the draft ordinance of 1900 should be disallowed by the proper authority

The condition referred to is —

> A licence shall be granted to any candidate producing a certificate from the Medical Board showing that that Board is satisfied that the candidate has attended one or more recognised hospitals in Malta or [illegible]

In seconding the adoption of the second of these recommendations Dr MACALISTER mentioned that in objecting to Section 5 of the draft ordinance the Council would not be going against the views of the Privy Council as the Government had already indicated that they were prepared to delete the words to which exception was taken

On the motion of the PRESIDENT, Dr MacAlister was authorised to inform the Privy Council of the General Medical Council's action in the matter

Registration of Foreign Graduates

On the motion of Sir JOHN BATTY TUKE, seconded by Dr MACALISTER, the Counc[illegible] from the Education Committ[illegible] diplomas granted by Italian [illegible]

> The Executive Committee have remitted to the Education Committee an application from a graduate of the University of Turin that his diploma may be recognised by the Council under Section 13 (1) of the [illegible] remitted to them
>
> Applications of a similar kind from graduates and licentiates of other Italian Faculties are not unlikely to be received by the Council, and the same necessity for further information will arise in regard to these [illegible] uncil [illegible] ncils, [illegible] omas [illegible] I m [illegible] may [illegible] the

The Council adjourned

MR. JOHN SYDNEY HICKS, M.D. Lond., a Cornishman, has been elected without opposition member of the Legislative Assembly, West Australia, for the Roebourne or north west district the expenditure of the society in the years 1895 and 1900, from which it appeared that between those years the number of patients had increased fivefold, while the cost of maintenance per patient had diminished by more than 50 per cent. —a result which was attributed entirely to the economical advantages arising under the colony system from dealing with increased numbers. This fact, the committee urged, might justly commend itself to the consideration of the charitable public as an additional reason for the further extension of the accommodation at the colony.

A CENTENARIAN.—Miss Sarah Dawes of St. Michell's Park, Bristol, died last week, aged 101 years.

A YOUNG Italian lady, Dr. Rina Monti, who has published several scientific papers and who gained a university gold medal, has been accepted by the University of Pavia as a Lecturer in Anatomy.

ATTEMPTED SUICIDE.—On May 29th a sailor, 21 years of age, was charged at Marlborough-street Police-court with attempting to commit suicide at the Middlesex Hospital. One of the nurses of the hospital stated that he was admitted on May 27th suffering from a swelling in his neck, and on the following day at 9 P.M. she saw that the chain which hangs over the bed for patients to raise themselves by was tied tightly round his neck. A police sergeant said that at the police station the accused asserted that he still intended to commit suicide and that his father had hanged himself by the same means in a London hospital 18 months ago. The accused was remanded.

DEATHS FROM LIGHTNING.—On May 29th an excursion party from Coventry (six in number) who were driving in a wagonette to Princethorpe, had reached the neighbourhood of Shelton-on-Dunsmore when a thunderstorm came on and they took shelter beneath a tree on the roadside. They were struck by lightning and all "fell down in a bunch." A man and a horse were killed and three adults and a little boy were severely injured.—On the same evening a Norfolk militiaman, recently invalided home from South Africa, was killed by lightning while sitting at the open window of a public-house at Grimston, near Lynn. Two companions were also struck, but they escaped with slight injuries.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The annual general meeting of this society was held on May 22nd, at 11, Chandos-street, London, W., Mr. Christopher Heath the President, being in the chair. From the report read by the secretary it appeared that during 1900 seven new members had been elected, 13 members had died, and four had resigned; the number of members at the end of the year was 280. Three widows and seven orphans had been elected, four widows had died, and four orphans had become ineligible for further grants; 47 widows and 14 orphans were in receipt of grants on Dec. 31st. The receipts available for grants and expenses were £3388 8*s.* 6*d* and the grants amounted to £3034 10*s.*, including the Christmas present of £531. The expenses were £244 1*s.* 8*d.* No legacy had been received. The following gentlemen were elected to fill the vacancies in the list of officers for 1901–1902: Dr. G. F. Blandford, treasurer; Mr. Sleeman, Mr. Elwin, Sir Hermann Weber, Mr. Stowers, Dr. Nix, and Dr. Palmer, directors. A grant of £26 under by-law 78 was made to a widow. The funded property of the society was reported as £98,350. Since January, 1901, 26 new members had been elected. A vote of thanks to the editors of the medical journals was carried unanimously. The proceedings were closed by a vote of thanks to the chairman.

BOOKS, ETC., RECEIVED.

ARROWSMITH, J. W., Quay-street, Bristol.
- Bath Waters: a Rational Account of their Nature and Use, with Special Reference to Gout, Rheumatism, and Rheumatoid Arthritis. By Preston King, M.D. Price not stated.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

BARKER, H. M., M.D. Aberd., L.R.C.P. Edin., M.R.C.S. Eng., has been appointed Deputy Medical Officer of Health of the Sandown Urban District, Isle of Wight.

BLACKBURN, VERNON K., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Assistant Resident Medical Officer to the Sheffield City Hospitals for the treatment of cases of infectious disease.

CLOWES, E. F., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed Certifying Surgeon under the Factory Acts for the Wootton-under-Edge District of Gloucestershire.

DAY, G., L.R.C.P. & S. Edin., has been appointed Senior Resident to the Bootle Borough Hospital.

Jacob, F. H., M.B. Lond., has been appointed Honorary Assistant Physician to the Nottingham General Hospital.

Macdonald, G. H. D., M.B. Aberd., has been appointed Officer of Health for Portlandshire, Victoria.

[illegible] promoted to Honorary Surgeon.

[illegible] Medical Officer of [illegible] rgeon to the [illegible] R.C.S.I., has [illegible] Certifying District of [illegible] outh Wales.

oung, R. W., M.R.C.S. Eng., L.S.A., has been appointed Medical Attendant on Aborigines at Ulladulla, New South Wales.

Vacancies.

r further information regarding each vacancy reference should be made to the advertisement (see Index).

rnwood House Hospital for the Insane, Gloucester.—Junior Assistant Medical Officer. Salary £150 (arising to £170), with board, &c.

thnal Green Infirmary.—Resident Locum Tenens for two months. Four guineas a week and allowances.

[illegible]—Junior House Surgeon [illegible] dging [illegible] Surgeon, single. Salary [illegible] Salary £80 per annum [illegible] sary.—House Surgeon [illegible] apartments, coals, gas, and [illegible]

lsea Hospital for Women, Fulham road, S.W.—Registrar [illegible] Surgeon, un[illegible] g, and washing [illegible] Salary £80, [illegible] geon. Salary to [illegible]—Lady House [illegible] coals, lodging, and wash[illegible]

ford Union, Suffolk (Lavenham District).—Medical Officer and Public Vaccinator. Salary £52 2s. and fees amounting approximately to £45.

unty Asylum, Carmarthen.—Junior Assistant Medical Officer, unmarried. Salary £130, advancing £10 yearly to £150, with furnished apartments board, washing and attendance, without stimulants.

unty Asylum, Prestwich, Manchester.—Assistant Medical Officer, unmarried. Salary £150 increasing to £250, with board, apartments, and washing.

unty Asylum Whittingham, Lancashire.—Junior Assistant Medical Officer, unmarried. Salary £150, increasing to £250, and on promotion to £300. Furnished apartments, board, washing, and attendance provided.

vonshire Hospital, Buxton Derbyshire.—Assistant House-Surgeon. Salary £80 per annum, with furnished apartments, board, and washing.

neral Infirmary Leeds.—Resident Obstetric Officer. Salary £50 a year, with board, lodging, and washing.

ahamstown Asylum and Chronic Sick Hospital, South Africa.—Assistant Medical Officer. Salary £250 per annum, with board and quarters. Free passage.

eat Northern Central Hospital.—Non resident Assistant House Surgeon for six months. Salary at the rate of £30 per annum, with luncheon and dinner.

y's Hospital.—Lecturer on Biology; also Demonstrator of Chemistry and Physics and of Chemistry and Toxicology.

mpstead Hospital.—Resident Medical Officer, for six months, renewable. Salary at rate of £120 with rooms, coals, and gas.

ston and Isleworth Urban District Council.—Medical Officer of Health. Salary £250.

ll Royal Infirmary.—Junior Assistant [illegible] £60, with [illegible]

man [illegible] mar [illegible] trar [illegible] fern [illegible]

[illegible] of Clyde.—Resident Medical Man. £40 per annum in addition to guaranteed Practice, and other emoluments.

ew Memorial Hospital.—House Surgeon (unmarried). Salary £100 per annum, with board and residence.

Kent and Canterbury Hospital.—Assistant House Surgeon, unmarried. Salary £60 a year, with board and lodging.

Leicester Infirmary.—Second Assistant House Surgeon. Salary £80 per annum, with board, apartments, and washing.

London Hospital Medical College.—Instructor of Anæsthetics and two Assistants.

Manchester Children's Hospital.—Assistant Surgeon. Honorarium of £50 per annum.

Norfolk and Norwich Hospital.—Assistant House Surgeon for six months. Honorarium £20, with board, lodging, and washing.

North Eastern Hospital for Children, Hackney-road, N.E.—House Surgeon for six months. Salary at rate of £80 per annum, with board, residence, and laundry.

Nottingham General Dispensary.—[illegible] £200 per annum, increasing by £15 [illegible] Resident Surgeons. Salaries £160 [illegible] £10 every year, furnished apart[illegible] fuel. Unmarried.

Paddington Infirmary.—Clinical Assistant and Second Assistant, unmarried, for six months. Honorarium of £36, with board, lodging, and washing.

Queen's Hospital, Birmingham.—House Surgeon for 14 months. Salary at the rate of £50 per annum, with board, lodging and washing.

Royal Alexandra Infirmary, Barbour Park, Paisley.—House Surgeon. Salary £60. Assistant House Surgeon. Salary £30; both with bed and board.

Royal Cornwall Infirmary.—House Surgeon, unmarried. Salary £100, increasing by £10 a year, with board (excluding stimulants) and apartments.

Royal Sea Bathing Hospital, Margate.—Assistant Resident Surgeon. Salary £60, with board and residence.

Royal Westminster Ophthalmic H[illegible] Strand, W.C.—H[illegible] [illegible] Demonstrator of [illegible]

Uni[illegible]

We[illegible]

Worksop Dispensary and Victoria Hospital.—House Surgeon and Dispenser. Salary £150 per annum, rooms, and attendance.

Births, Marriages, and Deaths.

BIRTHS.

Eustace.—On May 27th, at [illegible] Surgeon Lieute[illegible] the wife of [illegible]

Petter.—On June [illegible] Walter Petter, [illegible] the wife of [illegible]

Sadler.—On June [illegible] F. J. Sadler, M.B., of a daughter.

Sutcliff.—On May 31st, at Park Villa, Torrington, Devon, the wife of E. Harvey Sutcliff, M.B., of a son.

MARRIAGES.

Burnet—Penman.—At St. Thomas's English Episcopal Church, Edinburgh, on June 1st, by the Rev. H. J. Colclough, M.A., James Burnet, M.A., M.B., Ch.B., M.R.C.P.E., to Agnes, daughter of John Penman, Edinburgh.

Collinson—Gummer.—June 5th, at the Rotherham parish church, by the Rev. J. W. Goodall, M.A., vicar, Francis Charles Collinson, M.R.C.S., L.R.C.P., second son of Mr. Wm. Collinson, Rotherham, to Lilian Guest Gummer, eldest daughter of Mr. George G[illegible] J.P., [illegible]

Lister—[illegible] by t[illegible] M.R[illegible] Berth[illegible] Oak [illegible]

Naesmyth—Burrage.—On the 1st inst., at St. Paul's, Beckenham, [illegible] assisted by the Rev. Hubert Green, [illegible] R.C.S., L.R.C.P., younger son of [illegible], Bart., to Flora, younger daughter [illegible]

[illegible] thbert's Church, Allendale, on the [illegible] by the Rev. H. S. Stephenson, M.A., rector, William George Richardson, M.B., F.R.C.S., son of the late Edward Richardson, Cotfield House, Gateshead, to Sarah, daughter of George Arnison, Surgeon, Allandale.

Shaw—Braithwaite.—On June 4th, at the parish church Leeds, by the Rev. R. S. Medlicott, assisted by the Rev. H. T. S. Gedge, Kenneth Rodas Devaynes Shaw, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., Calverley, Leeds, to Margaret Eudora, elder daughter of James Braithwaite, M.D., of Leeds.

DEATHS.

Cayzer.—On May 29th, at his residence, Mayfield, Grassendale, Liverpool, Thomas Cayzer, M.R.C.S. Eng., in his 67th year.

Myrtle.—On the 2nd of June, at Harrogate, suddenly, of acute laryngitis, James Aitken Myrtle, M.D., in his 41st year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A QUESTION IN HOSPITAL ADMINISTRATION.

To the Editors of THE LANCET.

SIRS,—I should like to know if I was justified in the following. A patient in the hospital of which I am house surgeon developed erysipelas. I communicated with the relieving officer (as the man was a pauper), with the medical officer of health, the sanitary inspector, and the master of the workhouse. All my communications were delivered before 10 in the morning. The medical officer of health said that the borough sanitary authority were not liable for his removal, as the patient was a pauper and must be isolated by the Poor-law authorities under his (the medical officer of health's) supervision. The Poor-law authorities took no notice whatever and after waiting until five o'clock in the afternoon I sent the patient walking up to the workhouse (a short half-mile). The patient's temperature was normal and he felt strong, almost as usual, as it was only a very slight attack. We were having an operation for intestinal anastomosis shortly, so I deemed it urgent that the man should go, and as he could do so without risk to himself and no authority would (or did) remove him in a reasonable time I thought I must take the matter in my own hands. We have a large casualty department as well, thereby rendering his retention still more dangerous. Who is the proper authority to deal with infected paupers? The man suffered nothing by walking and was well in a week.

I am, Sirs, yours faithfully,

June 3rd, 1901. J. W. R.

*** The house surgeon incurred penalties for causing a person suffering from an infectious disease to be exposed in the public highway. But, under the circumstances, common-sense and equity, if not law, might sanction this act. Presuming erysipelas to be a notifiable and removeable disease in that district, the medical officer of health is the person to act in such cases, and he would incur the consequences of its non-removal. The patient being a pauper or not is no concern of his, even if it be competent for him to judge whether the person is or is not in point of law a pauper. It is very usual for infectious cases to be removed direct from the workhouse to the infectious diseases hospital, the authorities of the latter recovering the cost of maintenance from the Poor-law authorities afterwards. It is, for instance, the invariable custom at all the metropolitan workhouses and infirmaries. In view of such precedents, and the practice is a common one, it cannot for one moment be held to be an excuse for the non-removal of the case by the medical officer of health that the patient was a pauper, unless, of course, the medical officer of health has received specific and unmistakeable instructions from his board in writing. Then the latter assumes the whole responsibility. Such line of argument would be wholly foreign to the intention and meaning of the Infectious Diseases Acts which instituted infectious diseases hospitals to prevent the spread of infectious diseases among the poor and destitute. The history of all great epidemics shows that it is the pauper and the tramp who have initiated them.—ED. L

"MEMORIAL TO THE LATE DR. ARCHIBALD HAMILTON JACOB."

MUSCULAR STIFFNESS.

To the Editors of THE LANCET.

SIRS,—I shall be much obliged if you or any of your readers could tell me the address or addresses of places where treatment is given to those suffering from muscular stiffness—rheumatism. Is there now any such place in London where treatment similar to that of the Zander method, with the dry heat method in addition, is carried on? I am very anxious to know quickly if there is such a place, and any information you can give me will be much appreciated.

I am, Sirs, yours faithfully,

June 4th, 1901. SENEX.

*** Cases of rheumatism are treated by the dry heat method at the Tallerman Free Institute, 50, Welbeck-street, London, W. Possibly some of our readers can tell our correspondent of other places.—ED. L.

A WARNING.

To the Editors of THE LANCET.

SIRS,—On Tuesday last I was consulted by a man who was fairly well dressed though of dissipated appearacce, about 24 years of age, and who gave the name of White. He said he had just returned from Australia and had been sent to me by the proprietor of his hotel. After the examination, &c., the "patient" tendered a cheque for £5, from which I was to deduct the amount of my fee and hand him the balance in cash. This I declined to do in spite of the man's offer to be content with 10*s.* in the meantime. I subsequently learnt that, on leaving me, the man went to a neighbouring chemist, made purchases to the value of £1 8*s.*, tendered the same cheque, saying it was at my request that he asked him to cash it. I am glad to say he was again unsuccessful.

I am, Sirs, yours faithfully,

Weymouth-street, W., June 5th, 1901. CHAS. W. CHAPMAN.

"THE TREATMENT OF THREAD-WORMS."

To the Editors of THE LANCET.

SIRS,—In your annotation on the above topic in THE LANCET of May 11th, p. 1354, you mention personal cleanliness as the proper remedy for the disorder. This will, I fear, prove for the ordinary mother of out-patients a counsel of perfection and of small practical value. May I venture to supplement your advice by adding that free inunction of the anus with nitrate of mercury ointment every night for six weeks will usually eradicate the disease by destroying the oxyuris as it emerges from the bowel for the purpose of laying its eggs. Your readers are aware that only one generation of worms need be dealt with.

I am, Sirs, yours faithfully,

June 2nd, 1901. MEDICUS.

"SUGGESTIONS WANTED."

To the Editors of THE LANCET.

SIRS,—In reply to "Veldt's" query in THE LANCET of June 1st, 1901, p. 1582, *re* hyperidrosis, I beg to state that I have been a victim to sweating and I attribute my cure to taking one-grain doses of calomel three times a day, followed by a saline aperient.

I am, Sirs, yours faithfully,

June 1st, 1901. LATE OF THE VELDT.

WANTED—LANTERN SLIDES OF BACTERIA MOULDS.

To the Editors of THE LANCET.

SIRS,—Will any of your readers kindly inform me where I can procure lantern slides of bacteria, moulds, &c.?

I am, Sirs, yours faithfully,

Calcutta, May 15th, 1901. T. FREDERICK PEARSE, F.R.C.S. Eng.

CLINICAL MEDICINE IN GERMANY.

To the Editors of THE LANCET.

SIRS,—I would deem it a favour if any of your readers could inform me where in Germany one could obtain the best instruction in clinical medicine and especially in diseases of the chest under a well known specialist in that subject.

I am, Sirs, yours faithfully,

May 31st, 1901. OMACT.

"BETA-EUCAINE."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of May 25th, p. 1510, Dr. L. F. Leslie asked if anyone could throw light on an unsatisfactory after effect following the otherwise satisfactory anæsthetic action of beta-eucaine in a case of extraction of finger-nail. Dr. Leslie says: "The preparation of eucaine was freshly prepared by a chemist, and all instruments were sterilised immediately before use." I promptly wrote to Dr. Leslie and threw out two possible eventualities. 1. That perhaps the chemist had used the alpha instead of the beta-eucaine. The former being the more soluble and is therefore preferred from a dispensing point of view, but has, as it was shown in dentistry, the peculiarity of causing swellings in some cases which, although painless, will last for three or four days, and the alpha had for this reason to be substituted by the beta description which does not cause these swellings but is less soluble. 2. That in all probability the eucaine solution had not been sterilised by boiling, which may be done and is one of its' advantages over cocaine. In answer to this letter Dr. Leslie caused the chemist to send me a sample of the eucaine he had used and on examination at the research laboratory of Messrs. Schering at Berlin it was found that this specimen was indeed beta-eucaine, and, following my request, Dr. Leslie's case was further investigated by scientists on the subject with this very interesting result, which may be of general interest to your readers who may at any time meet with similar difficulties, as I do not believe that the facts are generally appreciated. This report reads as follows: "Considering that Dr. Leslie declares 'that the eucaine solution was freshly prepared by a chemist' it is no doubt the case that this solution was not previously sterilised by boiling, which should be done before injection and the liquid should be injected at body temperature. This is one of the precautions which should not be neglected; another is that Dr. Braun, one of the prominent authors on beta-eucaine as an anæsthetic, has recently pointed out to us that the least admixture of morphine which may result from the use of a syringe which would previously have been used for a morphine injection would be sufficient to cause swellings, so it also occurs when after careful washing morphine traces are still present in the syringe and the cannula. No doubt also other not easily controllable causes may play a part." Eucaine may be boiled without decomposition, which is not the case with cocaine solutions, but if the use of a morphine syringe has to be avoided it is a matter which should be carefully noted by the practitioner.

I am, Sirs, yours faithfully,

June 3rd, 1901. AUG. ZIMMERMANN.

◆

A. B.—Our correspondent is not sufficiently explicit with regard to hi first question to enable us to give him an answer. If he will send us a more detailed account of the circumstances we shall be better able to help him. The literature of deaf-mutism is extensive. Numerous references to papers will be found in Neale's "Digest," and the titles of books upon the subject will be found in catalogues of medical libraries

W H does not state the age of the girl, but he might apply to the Meath Home of Comfort, Westbrook, Godalming Surrey There is also an epileptic colony at Chalfont St Peter, the London office of which is at 12, Buckingham-street, Strand, W C

Hispid —Martindale's "Extra Pharmacopœia" gives some useful hints as to dispensing, but the most complete treatise upon the subject is "The Art of Dispensing," published at the offices of the *Chemist and Druggist* 42, Cannon-street, London, E C.

Luminiferous Ether would be glad if any reader could refer him to literature bearing on the subject of "colour-music." Reports to scientific societies &c. are chiefly wanted, but any literature bearing on the subject will be welcomed

J E. (Kingstown) —As the communication in question has not appeared in type the writer will understand that we do not consider it of sufficient interest.

P A —Our correspondent is advised to consult her usual medical attendant who will give her every information upon the subject.

E. B G —We should say that 5s would be a reasonable sum to charge

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS" and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor"

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423 Strand, W C, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c, should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

During the week marked copies of the following newspapers have been received —*Liverpool Daily Post, Yorkshire Post, Leeds Mercury Bristol Mercury Sanitary Record, Christian World, Shanklin Gazette, Reading Mercury, Hertfordshire Mercury City Press Mining Journal South African News, Birmingham Daily Post, Local Government Journal, Surrey Advertiser, Worksop Guardian, Weekly Free Press (Aberdeen), &c., &c.*

Communications, Letters, &c., have been received from—

A.—Mr. A. Percy Allan, Lond.; Mr. B. G. Advani, Hyderabad; Messrs. Arthur and Co., Lond.; Dr. J. F. Armstrong, South Shields; A B

B.—Mr. W. H Browne, Leeds; Mr. C. J. Burgess, Sheffield; Mr. C. Birchall, Liverpool; Messrs J. Bale, Sons, and Danielsson, Lond: B B. G.; Bridgwater Infirmary, Hon. Secretary of; Dr. A. A Breuer, Lond.; Dr. E. F. Buzzard, Lond. Barnwood House Hospital, Gloucester, Medical Superintendent of Dr. E. M. Brockbank, Manchester. Messrs Boulton and Paul, Norwich; Bolingbroke Hospital, Governors of; Messrs. Bates, Hendy, and Co., Reading, Messrs Baird Bros. Glasgow; Dr. D. M. Browne, Abersychan; Messrs. Burroughs, Wellcome, and Co., Lond; Mr. Clark Bell, New York.

C.—Mr. W. Clemmey, Bootle; Cortland Wagon Co., Lond., Messrs. Cassell and Co., Lond.; Messrs. Crossley and Co., Lond; Cheltenham General Hospital. Hon. Secretary of; Cookery and Food Exhibition, Director of, Dr. D. L. Cairn, Glasgow, Chester General Infirmary, Secretary of Mr. J. Campbell, Inverkip; Mr. H. Collier, Birmingham; Cadbury Bros, Ltd., Bournville, Dr. J. Gray Clegg, Manchester; County Asylum, Whittingham, Superintendent of, C. W.

D.—Dr S. Davenport, Ashford; Mr. H. G. Dixon, Lond.; Messrs. J. Defries and Sons. Lond.; Mr. H J Dunn, South Croydon, Mr. F. Dixon, Lond.; Mr. L Durlacher; Mr. T. Dixon, Lond.; Dr. S. Dick, Manchester.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris

AN ABSTRACT OF

The Croonian Lectures

ON

THE CHEMICAL SIDE OF NERVOUS ACTIVITY.

Delivered before the Royal College of Physicians of London

BY W. D. HALLIBURTON, M.D., F.R.C.P. LOND., F.R.S.,
PROFESSOR OF PHYSIOLOGY, KING'S COLLEGE, LONDON.

LECTURE I.

Delivered on June 11th, 1901.

AFTER thanking the College for the honour of the lectureship Dr. Halliburton alluded to the large number of times the nervous system had been selected as the subject of the Croonian Lectures, either from the histological, experimental, or clinical side. The chemical side had, however, been in the main neglected. Researches on the brain, the organ of the mind, had been most fruitful in yielding results which were useful to those who treated disease, but they had not unearthed the ultimate meaning of mental processes The scalpel and the microscope had not been successful in discovering the mind; one would also not expect to find it in the test-tubes of the chemist Nevertheless, there were a large number of interesting chemical facts in connexion with the nervous system which were daily becoming more numerous and were not devoid of pathological importance. These the lecturer wished to lay before the College, and he stated that he intended especially to dwell upon those researches which had been done either by himself or by workers in his laboratory during the last few years. He did so, not because he considered them to be of greater importance than work which had issued from other laboratories, but because he understood that one object of the Croonian Lectureship was to give an investigator the opportunity of presenting his own original work in a connected and orderly way before the medical public He expressed his thanks to those who had worked with him, particularly to Dr. F. W. Mott and Dr. T. G. Brodie Much of what he had to say would supplement and extend the chemical work which Dr. Mott laid before the College in his Croonian Lectures last year. The subject of his first lecture would be:—

THE GENERAL COMPOSITION OF NERVOUS STRUCTURES.

Dr. Halliburton first dwelt on the large quantity of water in these tissues; this is highest in the grey matter (from 80 to 90 per cent.), less in white matter (70 per cent.), and least in nerves (from 61 to 65 per cent). [These facts were illustrated by a number of analytical tables]

The solid materials of nervous tissues are extremely numerous. The most important and most abundant, and those of which we have most accurate knowledge, are the proteids and the phosphorised fats. The percentage of proteids is especially high. [Here the lecturer had recourse to analytical tables compiled from his own observations] In grey matter the amount of proteid comprises over 50 per cent. of the solids; this is what would be expected from the fact that protoplasmic structures are most abundant there In any nervous structure the amount of grey matter, of water, and of proteid vary directly the one with the others.

The proteids present are three in number; the most abundant is nucleo proteid (containing 0 5 per cent. of phosphorus); there is not much of this, however, in the white matter. The other two proteids are globulins, one of which coagulates at 47° C. and the other at 70° C. The neuro-globulin which coagulates at the lower temperature is analogous to the cell-globulin obtained from most protoplasmic structures. In view of hyperpyrexia, a subject which the lecturer intended to discuss at greater length later, particular attention was drawn to the low temperature at which neuro-globulin is converted into coagulated proteid.

The other important substance in the nerve-tissues is protagon, the phosphorised fat. On decomposition it yields two substances: one of these is lecithin, the other cerebrin or cerebrins. The cerebrins are sometimes called cerebrosides; they are nitrogenous glucosides, the sugar obtainable having been identified as galactose. The composition of lecithin was described in some detail, but the most important fact in relation to it is its difference from an ordinary fat An ordinary neutral fat on hydrolysis yields a fatty acid and glycerine. Lecithin on hydrolysis yields not only fatty acid and glycerine, but phosphoric acid and choline in addition. The phosphoric acid contains all the phosphorus of the original lecithin and the choline all its nitrogen. Choline is chemically an alkaloid — trimethyl oxyethyl-ammonium hydroxide. It is somewhat toxic and its importance lies in the fact that it is a substance which can be easily recognised by both chemical and physiological tests, and its presence indicates that lecithin, and therefore nervous tissues, have undergone disintegration

The lecture concluded with a brief account of the cerebro-spinal fluid. This fluid differs from ordinary lymph in many particulars, but it apparently plays the part of the lymph of the central nervous system. It is characterised by its low specific gravity, its clear watery character, its paucity in proteid, and the presence in it of an unknown reducing substance which is not sugar. A number of analyses were given, and special attention was directed to Dr StClair Thomson's well known case in which the fluid dripped from a patient's nostril and which furnished a unique opportunity where the absolutely normal fluid could be examined. The observations and experiments made with this fluid by Dr. Thomson in conjunction with Dr. Leonard Hill and the lecturer were given at some length. The importance of cerebro-spinal fluid from the pathological standpoint was that here the products of brain katabolism would naturally be looked for. The normal fluid, for instance, contains the merest traces of choline and of proteid, but in pathological conditions in which the disintegrative side of metabolism preponderates over the assimilative, these materials, the chemical evidence of nervous breakdown, are much increased in quantity.

LECTURE II.

Delivered on June 13th, 1901.

METABOLISM IN NERVOUS TISSUES.

THE evidence that nervous material is during activity in that state of unstable equilibrium which is designated by the term "metabolism" is rather circumstantial than direct. Nervous action stands apart from the action of most other tissues in the extraordinary economy of wear and tear which is noticeable. This is accounted for either by the fact that a very small amount of chemical change is necessary for the manifestation of activity or else that the anabolic side of metabolic phenomena is very evenly and rapidly balanced against the katabolic or disintegrative side. The signs of action which do exist are to be found mainly at the beginnings and endings of the fibres—i e., the cells in brain and cord and the end-organs in muscle and other peripheral structures—and hardly at all in the more passive transmitters of energy, the fibres themselves. The statement is usually made that nerve-fibres are not capable of exhaustion.

These facts coincide with the arrangements of the vascular supply; the centres are richly supplied with blood-vessels, but in a nerve these are comparatively insignificant. The necessity for an abundant supply of oxygen to the brain is seen from the rapidly fatal effects of cerebral anæmia, and Dr. L. Hill's experiments with methylene blue strikingly illustrate how oxygen is used up on cerebral activity. If an anæsthetised animal receives methylene blue by intravenous injection, any part of the brain thrown into action by electrical stimulation loses its blue tint, due to the formation of a colourless reduction product.

A number of observations on the reaction of nervous tissues were then described by Dr. Halliburton. The normal reaction is alkaline; at death it becomes acid, but on activity there is little or no evidence that acid is formed in nerve-fibres. This was carefully tested in some experiments performed in conjunction with Dr. Brodie on non-medullated nerves. These nerves were selected, as the possibly masking effect of a large mass of myelin would then be absent. As a result of excessive stimulation for many hours the nerves in question never became acid.

In nerve centres there is, however, a formation of acid products, especially where nerve-cells were situated. The lecturer next described Dr. A. Waller's experiments which have led him to the conclusion that carbonic acid is produced during the activity of nerve, and he discussed his interesting theory that the medullary sheath and axis cylinder are related nutritionally, so that the absence of fatigue is due to the re-integrating action of the medullary sheath. This view was supported by the experiments of Miss Sowton on non-medullated nerves in which the gradual disappearance of the electrical response on repeated stimulation indicates that fatigue could be demonstrated in nerves which did not possess a medullary sheath. As some doubt had been expressed in regard to the trustworthiness of the galvanometric response the lecturer had, in conjunction with Dr. Brodie, investigated the same problem by another method. The non-medullated nerves selected were those of the spleen, and the muscular contraction of the spleen was recorded plethysmographically. The general plan of the experiments resembled that adopted by Bowditch and others in the investigation of fatigue in medullated nerves; curare was not applicable as a blocking agent and the constant current, even when weak, produced of itself so much depression, and this lasted so long, that it also was given up. The best block ultimately found was cold. The experiments showed that fatigue did not occur or could not be demonstrated in the splenic nerves. Dr. Halliburton then proceeded:

Evidence of fatigue products can be found in the central nervous system by examining cerebro-spinal fluid. The word "metabolism" is so often associated with the activity of the proteid constituents of protoplasm that one is apt sometimes to forget that other materials frequently exhibit a similar alternate or simultaneous series of anabolic and katabolic phases. In nervous structures this is particularly true for the complex phosphorised molecules of protagon. The trace of choline found in normal cerebro-spinal fluid represents the small balance on the wrong (katabolic) side of the account. Further, physiological saline solution, the most harmless of all reagents, will extract choline from perfectly fresh nervous tissues, especially from grey matter, the most active portion of nervous material. All observers do not at present agree with me that choline is the most important substance which goes into solution in such extracts, but all are agreed on its presence, which is the main point. It is also the only organic substance which, up to the present, has been satisfactorily identified. The fact that it is obtained by such simple means indicates that the protagon or lecithin from which it is derived is in a labile condition.

The importance of micro-chemical methods was next insisted on. The most useful of these are those associated with the names of Golgi and Nissl. Golgi's silver-chrome method is one that had led to important results. It was on this method that the adherents of the neuron theory mainly relied. Much doubt had, however, been expressed as to its absolute trustworthiness, and certainly it was not nearly so sensitive and delicate a method as that of Nissl for demonstrating changes in nerve cells. The significance of Nissl's granules which were demonstrable by methylene blue formed the subject of the next section of the lecture. Though it is doubtful whether chromatolysis occurred during ordinary fatigue, there is no doubt that excessive activity and numerous other pathological processes are characterised by the disintegration and disappearance of Nissl's granules. Chemically the granules are composed of nucleo-proteid, and no doubt their presence is an indication of a store of energy-producing substance. The lecture concluded by a reference to sleep, nature's great restorer for exhausted "nerves." Dr. Halliburton said:

Chemical theories which explain sleep by the production of soporific substances—leucomaines, reducing substances, &c.—during waking hours depend upon the slenderest of evidence which will not stand rigid inquiry. Loeb's recent researches on rhythmical action in contractile tissues have shown that the stimulus to alternate periods of rest and action consists of certain ions. In order that rhythmic action may be maintained a nicely balanced admixture of ions must be present. It is just within the bounds of possibility that nerve-cells may be brought within the same category and that the phenomenon of alternate periods of wakefulness and sleep may in the future be found explicable by the comparatively simple action of inorganic substances or of their constituent ions.

Some observers have sought for the meaning of sleep by examining the brains of animals which have been more or less deeply narcotised. The moniliform swellings which can then be seen on the dendrites have been taken by Demoor and others to be evidence that the dendrons have retracted, and so connexions with other dendrons are interrupted. Lugaro, on the other hand, has failed to find these varicosities and has formulated another bio-physical theory of sleep which is the exact contrary of Demoor's. He maintains that the interlacing of dendrites is much more intimate during sleep than during consciousness, and he explains sleep by supposing that the definite and limited relationships between neurons no longer exists, and these are lost or rendered ineffective by the universality of the connecting paths. Such a divergence of views is easy to understand, for they depend upon observations made by a single method (Golgi's), and that not a very trustworthy one.

A more satisfactory investigation of the effect of anæsthetics on nerve-cells has been carried out by Dr. Hamilton Wright mainly in the physiological laboratory at King's College. The research is important because methods other than Golgi's, especially that of Nissl, have been employed as well. In rabbits and dogs the moniliform enlargements certainly are always seen. Lugaro failed to find them because the dogs he used were not anæsthetised for a sufficient length of time. Dogs are more resistant than rabbits to ether and chloroform, and changes in the nerve-cells are not noticeable until at least four hours' narcosis has been produced.

Owing to the chemical action of the drug on the cells the Nissl bodies have no longer an affinity for methylene blue and the cells consequently present what Wright calls a rarefied appearance; when this is pronounced the cells appear like skeletons of healthy cells. In extreme cases the cells look as though they had undergone a degenerative change and after eight or nine hours' anæsthesia in dogs even the nucleus and nucleolus lose their affinity for basic dyes. The change, however, is not a real degeneration and passes off soon after the disappearance of the drug from the circulation. Even after nine hours' deep anæsthesia there is not a cell which is permanently deformed; the branches no longer present varicosities and all the axis cylinders as tested by the Marchi method are healthy. The action of chloroform and ether is no doubt bio-chemical; the chemical action of the anæsthetic interferes with the normal metabolic activity of the cell-bodies and this produces effects on the branches of the cell. The moniliform enlargements seen during the temporary pseudo-degenerative effects produced by the drug are comparable to the similar swellings of the axis cylinder produced by hydration or some chemical change of that nature which occurs during the early stages of Wallerian degeneration. The enlargements, therefore, are not the primary cause of loss of consciousness, but are merely secondary results of changes in the cell-body.

Dogs and rabbits differ in their susceptibility to the influence of anæsthetics, and this corresponds to the readiness with which the histological changes just described are produced. The effects are probably the same in kind for all animals, man included, though they differ in degree. One should, however, be very chary in concluding that the artificial sleep of a deeply narcotised animal is any criterion of what occurs during normal sleep. The sleep of anæsthesia is a pathological condition due to the action of a poison; the drug reduces the chemico-vital activities of the cells, and unconsciousness is in a sense dependent on an increasing condition of exhaustion, which may culminate in death. The sleep of health, on the other hand, is not produced by a poison; it is rather the normal manifestation of one stage in the rhythmical activity of the nerve-cells, and though it may be preceded by fatigue or exhaustion it is accompanied by repair, the constructive side of metabolic action.

NOTIFICATION OF PULMONARY TUBERCULOSIS.—At the monthly meeting of the Teignmouth District Council held on June 3rd it was decided to draw the attention of the local medical men to the medical officer of health's suggestion that cases of pulmonary tuberculosis should be notified. The registrar of deaths was instructed to inform the medical officer of health of all deaths from tuberculosis.

STANDARDISATION OF CALMETTE'S ANTI-VENOMOUS SERUM WITH PURE COBRA VENOM:

THE DETERIORATION OF THIS SERUM THROUGH KEEPING IN INDIA.

BY GEORGE LAMB M.B. GLASG.,
CAPTAIN, INDIAN MEDICAL SERVICE,
AND
WILLIAM HANNA, M A., M.B. R.U.I., D.P.H. CANTAB
(*From the Research Laboratory, Bombay.*)

THE standardisation of an anti-venomous serum is of great practical as well as theoretical importance. It is the practical side of the question to which we propose to confine ourselves in this paper.

The snake venom which M. Calmette[1] employs both for the purpose of immunisation of his horses and for the purpose of standardisation of the serum recovered from these immune horses is a mixture of colubrine and viperine poisons, the former making up about 80 per cent of the mixture. A solution of this mixture is heated at about 73° C. for half an hour and then filtered. It is this mixed and heated poison which is employed at Lille for both the purposes above mentioned.

Myers[2] has correctly pointed out that as we have in all cases clinically to deal with intoxication by a pure venom, either colubrine or viperine, and also by an unheated venom, it is preferable, if the true value of this serum as a curative agent against snake-bite is to be determined, to use a pure unheated poison for its standardisation. The object, then, of our investigation was to ascertain as exactly as possible the neutralising power of Calmette's anti-venomous serum when tested with pure, fresh, and carefully dried cobra poison. Further, in consequence of the observations made by us in a recent case of cobra intoxication,[3] we have extended our investigations so as to ascertain if any deterioration of the serum takes place through keeping in this country. In another communication we hope to be able to record the results of similar experiments made with the venom of Russell's viper (*Daboia Russellii*)

The method of standardisation of the anti-venomous serum which we adopted in our experiments was the method now recognised as giving the most accurate results. It is based on the now almost generally acknowledged fact that snake-poison toxin and its antitoxin interact directly and that this neutralisation is, so far as our knowledge goes, independent of vital activity. The evolution of this method is briefly stated as follows The method which M. Calmette[4] recommends and still practises is the following:—The dose of venom (mixed and heated) which will kill a rabbit of two kilos in weight in from 15 to 20 minutes when injected into *the marginal vein of the ear is determined; then the* minimum amount of serum which will prevent death when injected intravenously five minutes before this dose is ascertained, which is done by experimenting with varying quantities of serum. If one cubic centimetre is able to accomplish this M. Calmette says that the serum contains 2000 immunity units per cubic centimetre or 20,000 per 10 cubic centimetres.

Martin of Melbourne[5] was the first to use the method of mixing the venom and serum *in vitro* before the injection In some early experiments with the poison of the Australian tiger snake (*Hoplocephalus curtus*) he used only a single lethal dose in estimating the curative value of Calmette's serum. However, in some later researches he recognised that this method was fallacious inasmuch as if the amount of serum was able to neutralise even a mere fraction of the single lethal dose the animal would recover even though the larger part of the poison remained unneutralised He therefore recommended the employment of at least 10 lethal doses.

Along with one of us Major D. Semple, R A.M.C.,[6] has pointed out that the following objections could be taken to Calmette's method: (1) that there is no direct estimation of *the amount of venom which a given quantity of serum will* neutralise;[7] and (2) that there is no estimation made of the amount of venom the injection of which an untreated animal is capable of surviving. Further, we showed that Calmette's test dose for the rabbit amounted to about three lethal doses for that animal. We thus gave a value for the serum in terms of its neutralising power and not as in the method used at Lille in terms of its preventive power. With such a small test dose as three lethal doses, unless careful attention be paid to the second objection mentioned above, it is evident that a much enhanced neutralising power would be given to the serum.

The next step in advance was made by Myers.[8] As previously mentioned this observer pointed out that in order to ascertain the strength of an anti-venomous serum for practical purposes it was *a priori* preferable to test it against a pure venom, such as pure cobra poison or pure Daboia poison. He further showed that it was preferable also to use unheated venom, inasmuch as heating at the temperature employed by M. Calmette causes important changes in cobra venom, altering it considerably from the natural poison as injected by a snake Further, Myers recommended that a cheap, small, *and susceptible* animal should be employed. He showed that mice of about 15 grammes in weight answer all requirements, and recommended that these animals should be used. He further designated Calmette's method as unscientific, inasmuch as by injecting the serum before the venom the completion of the reaction between these two bodies does not take place before they enter the blood-stream He showed that much more accurate results are attained when the poison and serum are mixed *in vitro* than by Calmette's method. Finally, he recognised the necessity of using a multiple, and if possible a large multiple, of *the minimum lethal dose.*

In the series of experiments which we have now to present these various points were kept carefully in view. We may preface the protocols by giving a short account of the method employed and of the general results obtained.

The animals which we used were rats from 115 to 120 grammes in weight These fulfil all the conditions indicated by Myers. They are cheap and the supply is abundant, while with care no difficulty is experienced in handling them At the same time they are extremely susceptible to cobra poison, as susceptible as, if not more so than, any of the other laboratory *animals Thus for a mouse of 15 grammes* Myers[9] states the minimum lethal dose of cobra venom to be 0 012 milligramme or in other words 0 8 milligramme per kilo. For rabbits Elliot[10] has found that a certain lethal dose of pure cobra poison injected subcutaneously is 0 7 milligramme per kilo. In our experiments we found that the minimum lethal dose of this poison for a rat of about 120 grammes was 0 04 or at the rate of 0 33 milligramme per kilo. Another reason for selecting rats was that horses' serum, even in large doses, has no lethal action on them as it has on mice. As in the course of our experiments large *doses of serum* had to be given this was an important point Great care was taken in choosing rats of one size for all experiments—viz, of about the weight mentioned above The venom used was pure, fresh, unheated cobra poison. This was collected from a number of living, full-sized, healthy cobras by "milking" the glands after the method practised by M Calmette. The poison was then thoroughly dried over lime and kept till used in an air-tight tube away from light Before weighing it was pounded in a mortar and was then again dried over sulphuric acid. A solution of this powdered venom in normal salt solution was made The strength of this solution was 0 1 per cent. When necessary a tenfold dilution of this material was employed All the solutions were freshly made, as required, so that no deterioration of the poison was possible through keeping in solution All injections were made in the inner side of the thigh.

Series No 1 was undertaken to determine the minimum lethal dose for a rat of from 115 to 120 grammes in weight.

[7] This is evident from the description of Calmette's method already stated From this it will be seen that the standard which he adopts is the weight in grammes of a rabbit which one cubic centimetre of serum can protect against a quantity of poison which would kill a control animal in 20 minutes.

[10] Brit. Med Jour, Feb 10th, 1900, p. 308.

A certain lethal dose was found to be 0·04 milligramme and the maximum non-lethal dose was found to be 0 035 milligramme.

The remaining series of experiments were undertaken with a view of determining the neutralising power of various samples of anti-venomous serum. These samples were of different ages and had been in India for varying periods of time. They had been stored in different places and had therefore been exposed to different degrees of heat. The test dose of venom which was used in all cases consisted of ten times the minimum lethal dose—i.e., 0·4 milligramme. This quantity was mixed *in vitro with varying amounts* of the serum to be tested. The mixture was allowed to stand at laboratory temperature (about 25° C.) for at least half an hour. All injections were made, as in the experiments detailed in Series No. 1, subcutaneously in the inner side of the thigh. In calculating *the amount* of venom which the serum had been able to neutralise or had failed to neutralise the maximum non-lethal dose—i.e., 0·035 milligramme—was deducted from the test dose in all cases.

In Series No. 2 a serum which had recently been received from Lille was used. We take this opportunity of thanking M. Calmette for his courtesy in placing this serum at our disposal. This sample was dated Sept. 17th, 1900. It arrived in Bombay on Oct. 14th of the same year. Our experiments with it were made between Nov. 10th and Dec. 5th. We are justified, therefore, in considering this as perfectly fresh serum, as fresh as it would be possible to get in this country. *A reference to the protocols will show* that 0 5 cubic centimetre was able to prevent death while 0 45 cubic centimetre did not accomplish this. In other words, 0·5 cubic centimetre of this serum was able to neutralise 0·4 − 0·035 milligramme = 0·365 milligramme—namely, 1 cubic centimetre could neutralise 0 73 milligramme. Working with a mixed and heated venom Semple and one of us[11] found that one cubic centimetre of fresh serum was able to neutralise 1 5 milligrammes of this mixed poison. This is the same value which M. Calmette attributes to his serum when this is expressed in terms of the neutralising power of the serum. Comparing these three results we see at once, therefore, the importance of testing the serum against a pure unheated venom and not with a mixed and heated poison.[12]

The serum employed to perform the experiments detailed in Series No. 3 was obtained by purchase from Messrs. Phillips and Co., chemists, Bombay. It bore the date May 8th, 1900. The vendors informed us that they had received it from Europe about the end of August, 1900, and that it had not been out of Bombay. Our experiments were made between Dec. 5th and 12th, 1900. It will be seen therefore that this serum had been in Bombay for about three months. One of these months—viz., October—is one of the hottest months of the year.

A reference to the protocols will show that 0·6 cubic centimetre was able to prevent death, while 0·5 cubic centimetre would not accomplish this. It is evident therefore that one cubic centimetre of this serum was able to neutralise 0 61 milligramme. This result would appear to point to a slight deterioration of the serum having taken place through keeping in Bombay, even for the short time mentioned above.

The serum used in Series No. 4 of our experiments was obtained from the Natural History Society of Bombay. We take this opportunity of thanking Mr. Phipson, the honorary secretary of that society, for his kindness in placing it at our disposal. This sample of serum was not dated. Mr. Phipson, however, thought that it had been in his possession for about four years. On reference to Lille, M. Calmette informed us that he did not know the exact age of the serum, but it was at least more than three years old. From the protocols it will be seen that although one rat which received 0 75 cubic centimetre of serum recovered after being very ill, the quantity of serum necessary to prevent a fatal result with certainty was 1·25 cubic centimetres. It is evident therefore that *one cubic centimetre of this serum was able to neutralise only 0·29 milligramme of pure cobra venom.*

The fifth series of *experiments detailed in the protocols* was made with serum which was sent to us by Captain Mitchell of Nasik. In view of the results obtained the history of this sample of serum is interesting. It was originally the property of the Bombay Natural History Society and was got from Europe at the same time as the serum used in Series No. 4 of our experiments. It was, therefore, more than three years old. Soon after its arrival in Bombay it was sent to Nasik. It was kept there till Captain Mitchell sent it to us in October, 1900. Our experiments with this serum were made between Oct. 16th and Nov. 1st, 1900. A reference to the protocols will show that 0·8 cubic centimetre was able to prevent death when our test dose was employed. In other words one cubic centimetre of this *serum was able to neutralise with certainty 0·46 milligramme* of pure cobra poison.

For Series No. 6 of our experiments the sample of serum was obtained from Lieutenant-Colonel Gimlette, I.M.S., residency surgeon, Indore. This sample was dated Oct. 17th, 1896. Its history was as follows. It was imported to India by Messrs. Smith, Stanistreet, and Co., chemists, Calcutta, arriving in this country about the end of August, 1899. It was sent to Indore on Sept. 6th of the same year. Colonel Gimlette despatched it to Bombay at the end of November, 1900, and our experiments were completed between Nov. 29th and Dec. 3rd. It will be seen, therefore, that for over a year it lay at Indore and was thus subjected to the great heat of this place during one hot season. A reference to the protocols will show that 1·7 cubic centimetres of this serum failed to neutralise the test dose, while two cubic centimetres were able to accomplish this. The rat which received this latter quantity was *ill* for a short time. We may take it therefore that two cubic centimetres were the amount which could neutralise just over nine lethal doses, or in other words that one cubic centimetre was able to neutralise only 0 18 milligramme of venom.

The experiments detailed in Series No. 7 of the protocols were made with a serum received from Mr. Hankin of Agra. This sample bore the date Sept. 17th, 1895. It had been stored in Agra for over four years. It was received in Bombay on Oct. 17th, 1900, and our experiments with it were completed between Nov. 27th and Dec. 10th. A glance *at the protocols will show that 2·5 cubic centimetres of this* serum—i.e., the largest amount used—were not able to prevent death when our test dose of 10 lethal doses was employed. From this it is evident that one cubic centimetre of this Agra serum could not neutralise even 0·14 milligramme of poison. The serum can therefore be said to have lost all neutralising power for practical purposes.

The serum employed in the eighth and last series of experiments detailed in the protocols was received from Lieutenant W. G Liston, I M.S., Civil Surgeon, Ellichpur, Berar. It was dated Nov. 7th, 1896. Lieutenant Liston had purchased it from Lille in September, 1898, and had brought it with him to India in the following month. During the hot seasons of 1899 and 1900 the serum had been subjected to the heat of Berar at two stations—viz., Hingoli and Ellichpur. It was sent to Bombay in December, 1900. The experiments made by us were completed between Dec. 10th and 14th. *From the protocols it will be seen that two cubic* centimetres of this serum failed to neutralise the test dose. We can therefore conclude that one cubic centimetre was not able to neutralise 0·18 milligramme of venom. It is unfortunate that no more serum was available to complete this series. It is, however, evident that like the Agra serum it had lost for all therapeutical purposes its power to neutralise pure cobra poison.

We may now pass on to consider some of the practical bearings which the data collated above and detailed in the protocols have on the standardisation of anti-venomous serum and on the therapeutics of cobra poisoning. First, our experiments conclusively prove Myers's statement that it is necessary in standardising this serum to use a pure unheated poison. Both in Calmette's method of standardisation and in the method followed by Semple and one of us a mixed venom containing about 80 per cent. of colubrine poison was employed. The solution of this mixture was heated at 73° C. for half an hour and was then filtered. The conclusion arrived at in both cases was the same—viz., that one cubic centimetre of serum was able to neutralise 1·5 milligramme of this venom. As this mixture contained only a fifth part of viperine poison it appeared justifiable to conclude that one cubic centimetre of serum would be able to neutralise at least about 1·2 milligrammes of pure cobra poison. Our experiments, however, have shown that such a hypothesis is not borne out by fact and that one cubic centimetre of serum can only neutralise about 0 7 milligramme of pure cobra venom.[13] Secondly, it is evident that any attempt to calculate the therapeutic dose of the serum can only be made when the exact measure of its power of neutralising a natural poison has been ascertained. Let us consider this point in some detail.

---

[11] Loc. cit.

[12] This comparison, as well as other similar comparisons to be detailed later, is made on the assumption that all [illegible] to slight initial differences in this neutralising power.

Calmette recommends that from 10 to 20 cubic centimetres[14] be given as the dose in all cases of bites from poisonous snakes. We shall see later that such a dose would probably be insufficient in some cases of cobra bite.

Semple and one of us[15] calculated that 15 cubic centimetres were sufficient to save a patient if this quantity were injected into the blood before the lapse of such period of time as may be required for the absorption of the lethal dose of venom. This calculation, however, was made on the following assumptions :—1. That the minimum lethal dose of cobra venom for a man of 30 kilos in weight was, as estimated by Fraser[16] about 31 milligrammes and that consequently we may take 30 milligrammes as the maximum non-lethal dose for an average man. 2. That a full-sized cobra can inject at each bite a quantity of venom which in the dried state amounts to from 30 to 45 milligrammes. These amounts have been demonstrated experimentally by *Calmette.*[17] *To save a man bitten by a cobra, injecting the* maximum quantity possible, we should therefore have to give an amount of serum capable of neutralising 45 – 30 milligrammes = 15 milligrammes of cobra poison. 3. That one cubic centimetre of serum was capable of neutralising one milligramme of pure cobra venom. This figure was arrived at by assuming that pure unheated cobra poison was not more than a third more deadly that the mixed venom which we employed. This mixture it will be remembered, contained 80 per cent. of colubrine poison, and one cubic centimetre of serum was able to neuralise 1 5 milligrammes of it. It is evident, therefore, that were these three assumptions correct 15 cubic centimetres of serum would be a safe dose to employ in all cases of cobra-bite. Our experiments, however, have demonstrated that one cubic centimetre of serum is only capable of neutralising about 0 7 milligramme of pure cobra venom, while Myers[18] from his experiments on mice makes the quantity neutralised by one cubic centimetre even less than this—viz , 0 6 milligramme. Now, basing the calculation on this fact—viz , that one cubic centimetre of serum can neutralise from 0 6 to 0 7 milligramme of cobra venom—and on the first two assumptions stated above, we arrive at the conclusion that instead of 15 cubic centimetres of serum, a dose of from 22 to 25 cubic centimetres would have to be given to prevent death from the bite of a full-sized cobra.

As we have already stated, one of the assumptions on which the above calculation is founded is that the minimum lethal dose of cobra venom for a man is as much as 31 milligrammes This assumption is based partly on the fact, experimentally shown by Calmette[19] and other observers, that for such animals as the guinea pig, the rabbit, the dog, the monkey and the ass the larger the animal the greater is the amount of cobra venom, weight for weight, required to cause death. This rule, however, does not hold good for all species of animals. Thus Myers[20] has shown that the minimum lethal dose of cobra poison for a mouse of 15 grammes in weight is 0 012 milligramme. If the rat were as susceptible to this poison as is the mouse the lethal dose for a rat of 120 grammes weight [illegible] We have, however, seen above [illegible] for a rat of this size is only 0 04 milligramme—namely, that the rat is at least twice as susceptible to cobra venom as the mouse.

In view of this fact it would seem expedient in estimating the dose of anti-venomous serum to be given in a case of cobra-bite to base our calculations on the assumption that man is as susceptible as the most susceptible animal with which experiments have been made—viz , the rat Assuming, then, that man is as susceptible as the rat, it is evident that the minimum lethal dose for a man of 60 kilogrammes in weight would be about 20 milligrammes. We can therefore calculate that if a cobra had injected the maximum amount of venom possible—viz , 45 milligrammes (an assumption which it would be necessary to make in every case of snake-bite)—the quantity of serum required to merely save the life of anyone receiving this injection would be the amount which was capable of neutralising at least 45 – 19 milligrammes = 26 milligrammes. This amount of fresh serum—namely, serum of which one cubic centimetre was able to neutralise about 0 7 milligramme of cobra venom, would be about 37 cubic centimetres It is interesting in this connexion to point out that Calmette[21] himself has arrived at the conclusion that the minimum lethal dose of cobra venom for a man is only about 10 [illegible] hypothesis it is evident that [illegible] centimetres of serum to save [illegible] maximum quantity of venom which a cobra can inject.

Our contention that 15 cubic centimetres of serum is quite an inadequate dose for the treatment of a case of cobra bite receives corroboration from consideration of the accidental case which occurred in this laboratory a short time ago[22] The only treatment employed in this case was the subcutaneous injection of anti-venomous serum. Immediately after the accident 18 cubic centimetres of old serum were injected. *This was the serum obtained from the Bombay Natural* History Society the neutralising power of which was tested in the experiments detailed in Series No 4 of the protocols. From a reference to the protocols it will be seen that one cubic centimetre of this serum was able to neutralise 0 29 milligramme of pure cobra venom. It follows, then, that 18 cubic centimetres of such a serum was equivalent to 7 5 cubic centimetres of fresh serum—that is, of serum one cubic centimetre of which was capable of neutralising 0 7 milligramme of venom. Our patient therefore received as a preliminary dose a quantity of serum equivalent to 7 5 cubic centimetres of a perfectly fresh serum. In spite of this injection well-marked general symptoms referable to the central nervous system set in from about two and a half to three hours after the accident The case in all probability would have had a fatal ending had not a second injection of fresh serum been given before the symptoms had progressed too far.

Now, in this case the poison from one gland only was injected. We can therefore conclude that 15 cubic centimetres of fresh serum would have been quite inadequate to have prevented the onset of symptoms of intoxication and probably would not have prevented death had the patient received the quantity of poison contained in both glands. Shortly after the onset of symptoms 10 cubic centimetres of comparatively fresh serum were injected. This serum was got from Messrs. Phillips and Co (*vide* Series No. 3 in the protocols). We have seen that one cubic centimetre of this serum was capable of neutralising 0 61 milligramme of cobra poison. The dose which was injected was therefore equivalent to 8 5 cubic centimetres of perfectly fresh serum such as was used in the experiments detailed in Series No. 2 of the protocols. Our patient therefore received in all a quantity of serum equivalent to 16 cubic centimetres of perfectly fresh material. All symptoms in this case, in which the bite was inflicted by only one fang, soon passed off after the second injection of serum Since, however, the second dose was given after some of the poison had already joined on to the central nervous system it is for *a priori* reasons necessary to conclude that a smaller dose would have sufficed if the whole quantity had been injected before the onset of any symptoms. On the other hand, it must be remembered that the cobra which inflicted this bite had been in captivity for some months and would not consequently yield as much poison as an ordinary snake in nature would do For is it an observation of common occurrence in this laboratory that a cobra newly caught will yield from 20 to 30 large drops of poison, while after he has been a captive for some time this quantity will have diminished to from six to 10 drops and in time to *nil*

From what we have stated above it is evident that the question of the dose of serum to be injected in cases of cobra bite turns upon factors which cannot be directly experimentally determined—namely, (1) upon the amount of poison which the snake has injected and (2) upon the amount of cobra venom which an average man can survive. In view of the fact, however, that in the treatment of any case of cobra-bite we must always estimate the dose of antivenine to meet the possibility of the snake having injected the maximum quantity possible—i e., about 45 milligrammes—and in view of the fact that man may be as susceptible, weight for weight, as the rat, or perhaps more susceptible, it seems to us, from the considerations put forward above, that a dose of from 30 to 35 cubic centimetres of fresh serum or the equivalent of this should be given in every case of cobra-bite. A larger dose would of course be necessary if symptoms had set in before the treatment was begun. At any rate the history of this case shows that a dose of about 15 cubic centimetres would be quite inadequate in most cases of cobra-bite.

---

[13] The serum which we used in these experiments although newly arrived in India had necessarily been subjected for a short time to the heat of the voyage out—viz , in the Red Sea and the Indian Ocean. A slight deterioration may thus have taken place. This, however, could only account for a small proportion of this great difference.

[14] This is the dose prescribed in the printed instructions sent out with every bottle of serum.

[22] THE LANCET, Jan. 5th, 1901, p. 25.

We may now pass on, in conclusion, to consider briefly the question of the deterioration which anti-venomous serum undergoes by keeping in India. The data bearing on this subject are contained in detail in the protocols, Series No. 2 to No. 8 inclusive. These data may be briefly summarised in tabular form as follows:—

TABLE I.—*The Deterioration of Anti-venomous Serum by Keeping in India.*

Series in protocols.	Age of the serum.	Length of time in India.	Where kept in India.	Neutralising power.	Remarks.
No. 2	Two months.	One month.	Bombay.	1 cubic centimetre neutralised 0·73 milligramme.	This serum may be regarded as perfectly fresh serum.
No. 3	Seven months.	Three months.	Bombay.	1 cubic centimetre neutralised 0·61 milligramme.	—
No. 4	Over three years.	About three years.	Bombay.	1 cubic centimetre neutralised 0·29 milligramme.	—
No. 5	Over three years.	About three years.	Nasik and Bombay.	1 cubic centimetre neutralised 0·46 milligramme.	It is uncertain how long this sample had been in Bombay and how long in Nasik.
No. 6	Four years.	One and a quarter years.	Indore.	1 cubic centimetre neutralised 0·18 milligramme.	—
No. 7	Five years.	Over four years.	Agra.	1 cubic centimetre failed to neutralise 0·14 milligramme.	—
No. 8	Four years.	Two and a quarter years.	Bombay and Berar.	1 cubic centimetre failed to neutralise 0·18 milligramme.	In Bombay six months and in Berar one and three-quarter years.

The protective power ascribed by M. Calmette to al samples of sera sent out from Lille is 20,000 units per 10 cubic centimetres. We may, therefore, assume that all brews when fresh possess practically the same neutralising power (*vide* Footnote 12). A study of the above table shows that a progressive deterioration takes place from keeping the serum in India. Thus it will be noticed on the one hand that while the serum which was seven months old and had been in India for only three months (Series No. 3) already showed a slight diminution in its neutralising power, on the other hand, the sera which had been kept for some years in the Berar (Hingoli and Ellichpur), i.e., Series No. 8, and in Agra, i.e., Series No. 7, had practically lost all neutralising power, and the sera which had been stored at Indore, Bombay, and Nasik had detriorated to a considerable extent but had not completely lost all neutralising power.

Let us consider for a moment the climatic conditions as regards temperature which prevail at these different places. In the cold season Agra and the Berars have a comparatively low temperature; but for three or four months of the year the heat in these districts is excessive, the maximum temperature in the shade being seldom below 105° F. and often reaching 110° F. and over. Indore also has a severe hot season and a comparatively cool "cold" season, a similar climate in fact to that of Berar, although, perhaps, the maximum temperature does not reach so high as in the other two cases. The great neutralising power of the serum which had been kept at Indore, compared with the samples kept at Berar and Agra, can be accounted for by the fact that the former sample had been subjected to this great heat for only one hot season, while the sera kept at Berar and Agra had been stored in these districts during two and four hot seasons respectively.

The results obtained with Series No. 4 and Series No. 5 are especially interesting. Both these sera were of the same age and were imported to Bombay at the same time. One sample—viz., No. 5—had been stored for a considerable time at Nasik after Bombay. Now, the temperature of Nasik during the cool season of the year is much lower than is that of Bombay. On the other hand, during the hot months, March to May inclusive, the maximum shade temperature of Nasik is only slightly lower than is that of Bombay, while the minimum temperature is much lower. On the whole, therefore, we may take it that the serum which had been kept at Nasik had not been subjected to nearly such a high mean temperature during the year as had that serum which had been stored in Bombay. In consequence, the neutralising power of the former was more than a half greater than the neutralising power of the latter. We may conclude then from these data that anti-venomous serum undergoes a progressive and fairly rapid deterioration when stored in hot climates, and that this deterioration is greater and more rapid the higher the mean temperature to which it is subjected. The practical bearings of the results of these observations are so patent as to require no further discussion.

PROTOCOLS.

Series No. 1.—The poison used was carefully dried, pure, fresh cobra venom. It was unheated. A 0·1 per cent. solution in sterile normal saline solution was made. Ten-fold and hundred-fold dilutions of the original solution were used when necessary. The weights refer to the original dried venom. All rats were carefully selected of about 118 grammes weight. The injections were made subcutaneously in the inner side of the thigh.

TABLE II.—*Experiments to determine the Minimum Lethal Dose of Pure Cobra Venom for a Rat of about 118 grammes.*

Animal.	Amount of dried venom in milligrammes.	Result.
Rat 1	0·1	Died within 2 hours.
" 2	0·09	" " "
" 3	0·08	" " "
" 4	0·07	" " 3 "
" 5	0·06	" " "
" 6	0·05	" " "
" 7	0·05	" " "
" 8	0·045	Very ill for 24 hours; died in four days.
" 9	0·04	Died in 3¼ hours.
" 10	0·04	" 2¼ "
" 11	0·035	Ill for 16 hours; recovered.
" 12	0·035	" 6 " "
" 13	0·03	Slightly ill for 3 hours; recovered.
" 14	0·03	No symptoms.
" 15	0·025	" "
" 16	0·02	Slight symptoms; recovered.
" 17	0·01	No symptoms.
" 18	0·005	" "

From the above table it appears, then, that 0·04 milligramme is a certain lethal dose and that 0·035 milligramme is a dose which a rat of this size can survive—i.e., a maximum non-lethal dose. In the series of experiments No. 2 to No. 8, detailed hereafter, 10 lethal doses—namely, 0·4 milligramme—were mixed *in vitro* with varying amounts of sera of different ages and which had been kept under different conditions of temperature. The mixtures were allowed to stand at laboratory temperature (about 25° C.) for at least half an hour and were then injected subcutaneously in the inner side of the thigh. Carefully selected rats of about 118 grammes were used in all cases. In calculating the amount of venom which the serum had been able to neutralise or had failed to neutralise the maximum non-lethal dose—

namely, 0 035 milligramme—was deducted in all cases. These series are as follows.

Series No. 2.—The serum used in this series of experiments was received from Lille in October, 1900. It was dated Sept. 17th, 1900 The experiments were completed between Nov. 10th and Dec. 5th.

TABLE III.—*Experiments to ascertain the Amount of Venom which One Cubic Centimetre of Fresh Serum newly imported was capable of neutralising.*

Animal.	Amount of dried venom in milligrammes.	Amount of serum in cubic centimetres.	Result.
Rat 1 ...	0·4	0 15	Died in 5 hours.
,, 2 ...	0 4	0 2	,, 10½ ,,
,, 3 ...	0·4	0·2	,, 7½ ,,
,, 4 ...	0 4	0 2	,, 2¾ ,,
,, 5 ...	0·4	0 2	Died within 48 hours.
,, 6 ...	0·4	0 25	Died in 2¾ hours.
,, 7 ...	0 4	0·25	Died within 17 hours
,, 8 ...	0·4	0 25	,, ,, 5 ,,
,, 9 ...	0 4	0 3	Very ill for 48 hours, recovered.
,, 10 ...	0 4	0 3	Died in 5 hours.
,, 11 ...	0·4	0·3	,, 2¾ ,,
,, 12 ..	0 4	0·3	Died within 5 days.
,, 13 ...	0·4	0 35	,, ,, 48 hours.
,, 14 ...	0 4	0 35	,, ,, ,, ,,
,, 15 ...	0·4	0 35	Died in 17 hours.
,, 16 ...	0 4	0·4	Died within 40 hours
,, 17 ...	0 4	0·4	Ill for 5 days; recovered.
,, 18 ...	0 4	0 4	Died within 48 hours.
,, 19 ...	0·4	0 45	,, ,, 3 days.
,, 20 ...	0 4	0·45	Died after 8 days
,, 21 ...	0 4	0 5	No symptoms.
,, 22 ...	0 4	0·5	Ill for 2 days; recovered.
,, 23 ..	0·4	0 6	,, ,, ,,
,, 24 ...	0·4	0·7	No symptoms.

From the above series we can conclude that 0 45 cubic centimetre of this serum failed to neutralise with certainty 0 4 — 0 035 milligramme = 0 365 milligramme, while 0 5 cubic centimetre could neutralise this amount. In other words, one cubic centimetre was able to neutralise 0 73 milligramme.

Series No 3.—The serum used in this series was dated May 8th, 1900 It was purchased from Messrs. Phillips and Co., chemists, in Bombay, who had received it from England about the end of August. The experiments were completed between Dec 5th and 12th. The serum had, therefore, been in Bombay during one of the hottest months of the year—viz., October.

TABLE IV.—*Experiments to ascertain the Amount of Venom which One Cubic Centimetre of Comparatively Fresh Serum was capable of neutralising.*

Animal.	Amount of dried venom in milligrammes	Amount of serum in cubic centimetres	Result.
Rat 1 ...	0·4	0 2	Died in 2 hours.
,, 2 ...	0·4	0 3	,, ,, ,,
,, 3 ...	0 4	0 4	Died within 42 hours.
,, 4 ...	0·4	0 5	,, ,, ,, ,,
,, 5 ...	0 4	0 5	,, ,, 46 ,,
,, 6 ...	0·4	0 6	Ill for one day; recovered.
,, 7 ...	0·4	0 6	No symptoms.
,, 8 ..	0·4	0·7	,, ,,
,, 9 ...	0·4	0·7	,, ,,
,, 10 ...	0 4	0·8	,, ,,

From the above series we can conclude that 0 5 cubic centimetre of this serum failed to neutralise 0 4 — 0 035 milligramme = 0 365 milligramme, while 0 6 cubic centimetre could neutralise this amount at least—namely, that one cubic centimetre was able to neutralise 0·61 milligramme.

Series No. 4—This serum had been in the possession of the secretary of the Bombay Natural History Society for at least three years. M. Calmette informed us that it was at least three years old, probably more.

TABLE V.—*Experiments to ascertain the Amount of Venom which One Cubic Centimetre of a Serum which had been in Bombay for over Three Years was capable of neutralising*

Animal.	Amount of dried venon in Milligrammes.	Amount of serum in cubic centimetres.	Result.
Rat 1 ...	0 4	0 25	Died in 1½ hours.
,, 2 ...	0·4	0 5	,, ,, ,,
,, 3 ...	0 4	0 75	,, 3 ,,
,, 4 ..	0·4	0·75	Very ill for 48 hours; recovered.
,, 5 ...	0 4	0·85	Died within 36 hours.
,, 6 ...	0 4	1 0	Died in 6½ hours.
,, 7 .	0 4	1 0	,, 9 ,,
,, 8 ...	0·4	1 0	*Ill; recovered.*
,, 9 ...	0·4	1·15	Died after 3 days.
,, 10 ...	0 4	1·25	No symptoms.
,, 11 ...	0 4	1 5	,, ,,

From the above series of experiments we can conclude that 1·15 cubic-centimetres of this serum failed to completely neutralise 0 4 — 0 035 milligramme = 0 0365 milligramme, while 1 25 cubic-centimetres did neutralise this amount at least. Therefore, one cubic centimetre of this serum was able to neutralise 0 29 milligramme.

Series No 5.—The serum used in this series of experiments was got from Captain Mitchell of Nasik. It was imported to India at the same time as the serum used in the experiments detailed in Series No. 4. After being stored in Bombay it was sent to Nasik. The exact date when this happened cannot be ascertained as no record was kept of the event It was received at the laboratory from Nasik in October, 1900. The experiments were completed between Oct. 16th and Nov 13th

TABLE VI.—*Experiments to ascertain the Amount of Venom which One Cubic Centimetre of a Serum of the same age as that used in Series No 4 but which had been kept for most of the time in a comparatively cool place, was capable of neutralising*

Animal.	Amount of dried venom in milligrammes	Amount of serum in cubic centimetres	Result.
Rat 1 ...	0·4	0 25	Died within 3½ hours.
,, 2 ...	0 4	0 25	,, ,, 3 ,,
,, 3 .	0 4	0 25	,, ,, 7 ,,
,, 4 ...	0 4	0 3	,, ,, 4 ,,
,, 5 ...	0 4	0 35	,, ,, 4½ ,,
,, 6 ..	0 4	0·4	,, ,, 4 ,,
,, 7 ...	0 4	0 45	,, ,, 6 ,,
,, 8 ...	0 4	0 5	,, ,, 14 ,,
,, 9 ...	0·4	0·5	,, ,, 4¾ ,,
,, 10 ...	0 4	0 5	Very ill for 24 hours; recovered.
,, 11 ...	0 4	0 55	Died within 40 hours
,, 12 ..	0·4	0 6	,, ,, 50 ,,
,, 13 .	0 4	0·65	,, ,, 54 ,,
,, 14 ...	0 4	0·7	,, ,, 30 ,,
,, 15 ...	0 4	0·7	Ill, recovered
,, 16 ...	0 4	0·75	No symptoms.
,, 17 ...	0 4	0·75	Died within 8 days.
,, 18 ...	0 4	0·8	No symptoms.
,, 19 ...	0 4	1·0	,, ,,
,, 20 ...	0 4	1·25	,, ,,
,, 21 ...	0 4	1·5	,, ,,

From the above series of experiments we can conclude that 0 75 cubic centimetre of this serum did not completely neutralise 0 4 – 0 035 milligramme = 0 365 milligramme, but that 0 8 cubic centimetre was able to do this. It is evident, therefore, that one cubic centimetre of this sample could neutralise 0 46 milligramme.

Series No. 6.—This serum was dated Oct. 17th, 1896. At the time of our experiments it was therefore five years old. It was imported to India in September, 1899. It arrived in Indore the same month and was kept there till November, 1900, when it was sent to Bombay. The experiments were completed between Nov. 27th and Dec. 3rd.

Table VII.—*Experiments to ascertain the Amount of Venom which One Cubic Centimetre of Serum received from Lieutenant-Colonel Gimlette of Indore was able to neutralise.*

Animal.	Amount of dried venom in millegrammes	Amount of serum in cubic centimetres.	Result.
Rat 1 ...	0 4	0 5	Died in 2 hours.
" 2 ...	0 4	0 6	" " "
" 3 ...	0 4	0 7	" 1¼ "
" 4 ...	0 4	0 8	" " "
" 5 ...	0 4	0·9	" 2 "
" 6 ...	0 4	1 0	" 1¾ "
" 7 ...	0·4	1·1	" 20 "
" 8 ...	0 4	1·2	" " "
" 9 ...	0 4	1·3	" 2¼ "
" 10 ...	0 4	1 4	" 7½ "
" 11 ...	0 4	1 5	" 19 "
" 12 ...	0.4	1 6	" 90 "
" 13 ..	0 4	1·7	Died within 67 hours.
" 14 ...	0 4	2 0	Ill for 2 days; recovered.

From the above series of experiments we can conclude that two cubic centimetres were the minimum amount of serum which was able to neutralise 0 4 – 0 035 milligramme = 0 365 milligramme. In other words, one cubic centimetre was able to neutralise 0·18 milligramme.

Series No 7.—This sample of serum bore the date Sept 17th, 1895. Mr. Hankin informed us that he had kept no record of the exact date when he received this sample of serum, but that he had little or no doubt that he received it in the year in which it was prepared. We may, therefore, take it that this serum had been in Agra for over four years.

Table VIII.—*Experiments to ascertain the Amount of Venom which One Cubic Centimetre of Serum received from Mr. Hankin of Agra was able to neutralise.*

Animal.	Amount of dried. venom in milligrammes	Amount of serum in cubic centimetres.	Result.
Rat 1 ...	0 4	0 7	Died in 5 hours.
" 2 ...	0 4	0 8	" " "
" 3 ...	0 4	0·9	" 8 "
" 4 ...	0 4	1·0	Died within 48 hours.
" 5 ...	0 4	1 1	Died in 3¾ hours.
" 6 ...	0 4	1 2	" 9 "
" 7 ...	0 4	1 25	" 19 "
" 8 ...	0 4	1 3	" 9 "
" 9 ...	0 4	1 4	" " "
" 10 ...	0 4	1 4	" 30 "
" 11 ..	0 4	1 5	No symptoms
" 12 .	0·4	1·5	Died within 18 hours
" 13 ..	0 4	1·5	Died in 38 hours.
" 14 ..	0 4	1·6	Died within 22½ hours.
" 15 ...	0 4	1 6	Died in 18 hours.
" 16 ..	0 4	1 7	Died within 18 hours
" 17 ...	0 4	1 7	Died in 16¾ hours.
" 18 ...	0 4	1 8	Died within 18 hours.
" 19 ...	0 4	1 9	" " "
" 20 ...	0 4	2·0	Died in 24 hours.
" 21 ...	0 4	2·0	Died within 17 hours.
" 22 ...	0 4	2 25	" " "
" 23 ...	0 4	2 5	Died in 46 hours.

From the above series of experiments we can conclude that 2 5 cubic centimetres of this serum could not neutralise 0 4 – 0 035 milligramme = 0 365 milligramme. It is evident, therefore, that one cubic centimetre could not neutralise even 0 14 milligramme.

Series No. 8.—This serum was dated Nov. 7th, 1896. It was purchased from Lille by Lieutenant Liston, I.M.S , in September, 1898. It was imported to India the following month. For six months it was kept in Bombay, but during the hot season of 1899 and 1900 it was exposed to the great heat of Berar. It was sent to Bombay in December, 1900. The experiments were completed between Dec. 10th and 14th, 1900.

Table IX.—*Experiments to ascertain the Amount of Venom which One Cubic Centimetre of Serum received from Lieutenant Liston, I.M.S., Ellichpur, Berar, was capable of neutralising.*

Animal.	Amount of venom in milligrammes	Amount of serum in cubic centimetres	Result.
Rat 1 ...	0 4	0·5	Died within 3½ hours.
" 2 ...	0 4	0 8	" " " "
" 3 ...	0 4	1·0	" " " "
" 4 ...	0 4	1·25	Died in 22 hours.
" 5 ...	0 4	1·5	Died within 42 hours.
" 6 ...	0 4	1·75	" " 50 "
" 7 ...	0 4	1 75	" " 48 "
" 8 ...	0 4	2·0	" " 42 "

From the above series of experiments we can say that two cubic centimetres of this serum failed to neutralise 0 4 – 0 35 milligramme = 0·365 milligramme—namely, that one cubic centimetre could not neutralise 0 18 milligramme.

THE FEEDING OF DIPHTHERIA PATIENTS, WITH SPECIAL REFERENCE TO CHILDREN AND SEVERE CASES.

By R. G. KIRTON, M.D. Lond.,
SENIOR ASSISTANT MEDICAL OFFICER, BROOK FEVER HOSPITAL, SHOOTERS HILL.

In the treatment of diphtheria the feeding is of great importance, while at the same time it is attended with the greatest difficulty, owing to the inability of many patients to take or to retain nourishment given by the mouth. So much depends upon the nurse that it is essential to obtain the best nursing available. Feeding may be carried out by (1) the mouth; (2) the nasal tube; (3) the rectum; and (4) subcutaneous injections. In all cases, where practicable, feeding should be performed by the mouth. Certain conditions, however, render mouth feeding impossible or inadvisable. Chief amongst these are the following: (1) inability to swallow owing to pain or faucial swelling; (2) some cases of regurgitation, which will be referred to later; (3) entrance of food into the larynx in spite of slow and careful feeding indicated by the patient coughing when fed; (4) in certain cases, owing to struggling, the time taken and the exhaustion consequent on mouth feeding; and (5) continued vomiting—(*a*) vomiting may be present almost from the onset of diphtheria; (*b*) early vomiting, commencing about the middle or end of the second week; and (*c*) late vomiting, which occurs after some weeks of the disease. Generally speaking, vomiting which begins early is of graver import than that which starts late in the disease. It is well to remember that cases occur in which patients can be fed with a nasal tube without vomiting, although they vomit when fed by the mouth. In some this is probably due to distaste for their nourishment.

I.—Mouth Feeding.

In the early stages of diphtheria milk should be the chief article of food. It should be given either mixed with some diluent, as barley water, or in such form as Benger's or Mellin's food. It may be given hot or cold, sweetened or flavoured with tea, coffee, or cocoa As a rule children prefer milk sweetened, and this is probably a cause of some taking Mellin's food readily but objecting to diluted milk. Adults on the other hand, prefer milk flavoured. Children (and the bulk of the cases consist of children) on admission to hospital are usually fed every three or four hours. They will take from four to five ounces of milk each feed. This is diluted with a certain amount of barley water. The proportion of barley water added varies; usually it is in the ratio of one part to three parts of milk. Severe cases and infants up to about two years are fed every two hours and often will not take more than two ounces at a time. Children, even when they have membrane on their throats, will take their nourishment fairly well, but when the membrane has peeled off they sometimes have difficulty and pain in swallowing, and need a lot of persuasion even to take a small quantity of nourishment by the mouth. At first very few children are willing to drink out of a feeder. They much prefer a small medicine-glass or a teaspoon. All nourishment should be measured, and this specially so in severe cases. In cases which progress favourably, and where there are no special indications against it, the milk may in a short time be supplemented by other forms of nourishment, and the patient may soon return to an ordinary diet which should be both light and nutritious. Severe cases should be kept on a slop or modified slop diet for some little time longer than mild cases.

Regurgitation, &c.—Children with regurgitation must be fed very slowly. On no account should they be allowed to feed themselves. When regurgitation persists even with slow feeding all liquids should be thickened. Thus the milk may be given in the form of thick Benger's food, milk arrowroot, or a certain amount may be given as milk jelly, made by the addition of isinglass to the milk. Milk jelly can be made equally well with peptonised milk and is by no means unpalatable. Unfortunately, children often do not care for milk jelly. It is generally more liked in summer than in winter. Eggs may be tried as a suitable article of diet, provided they are assimilated, and sometimes patients with regurgitation are able to swallow them, if lightly boiled and made into a paste with bread crumbs. There are some patients who can take solids comfortably by the mouth, but are quite unable to swallow liquids. Others, owing to the length of time taken in feeding, are unable to take sufficient nourishment by the mouth In these cases mouth feeding should be supplemented by nasal feeding, or, if necessary, by rectal feeding. In others, again, nothing can be taken by the mouth. These remarks on cases with regurgitation apply equally well to patients who cough on feeding But here I think it is advisable that feeding by the mouth be left off earlier than in cases where regurgitation is the difficulty.

Vomiting.—Some patients suffering from diphtheria are inclined to retch and to vomit from the first. Sometimes this may be due to previous injudicious feeding or causes distinct from the diphtheria. It is best not to press these cases with nourishment at first. They should only have small quantities of peptonised milk, say, one ounce or less, hourly. Should the vomiting persist, feeding by the mouth should be stopped and other modes of feeding substituted. If the vomiting cease on the milk being peptonised the quantity may be cautiously increased, finally the peptonisation omitted, and the patient slowly be allowed to return to an ordinary milk diet Sometimes patients will take and retain water, raw-meat juice, or white of egg and water, although they reject peptonised milk. Raw meat juice or white of egg may be added to the peptonised milk if it is retained. Bread jelly, made as described by Dr. Cheadle, may be also tried. Early and late vomiting should be treated on the same lines as above. Generally, however, feeding by the mouth has to be entirely omitted for a time and rectal alimentation substituted. Vomiting is sometimes preceded by retching—a valuable indication to limit the amount and to alter the kind of nourishment, if necessary to go back to a strict milk diet and to have the milk peptonised. Occasionally hot applications to the epigastrium are of use in controlling vomiting to a certain extent.

Severe cases.—In cases of severe diphtheria, in which vomiting ultimately supervenes, the period previously to this may be quite free from vomiting. In such cases the milk should be supplemented by beef-tea, raw meat juice, eggs beaten up and mixed with a little brandy and milk—a good mixture being one egg, a little powdered sugar, half an ounce of brandy, and milk to two ounces. This may be given in small portions over 12 or 24 hours. The nourishment should be given in small quantities at frequent intervals. Great care must be taken to satisfy oneself that the nourishment taken is absorbed. These are cases in which one anticipates early or late vomiting, when the feeding will become more and more difficult. Therefore, if possible, they should be fed up with due care previously to the onset of vomiting.

Stimulants.—The administration, when indicated, of alcoholic stimulants is often beset with difficulty owing to the frequency with which vomiting follows their use. Brandy is the most generally suitable form, and in some cases can be given in definite amount daily without being rejected. Many children, however, apart from vomiting, show a great distaste for it In many cases it is best given as symptoms arise indicating its need. Since it is often necessary to give it quickly, I think it wise to allow an experienced nurse to give it on her own initiative and to inform the medical attendant of this later Champagne can be taken in some cases where brandy is rejected.

II.—NASAL FEEDING.

The following conditions render nasal feeding adviseable: (1) inability to swallow from regurgitation, paralysis of muscles of deglutition, &c.; (2) [illegible] due to entrance of food into the [illegible] in tracheotomy cases; (3) cases [illegible] the mouth, but do not when fed through the nose; (4) cases exhausted by mouth feeding, but not when nasal-fed (amongst these must be numbered cases in which mouth feeding takes a very long time); and (5) moral effect. These suggestions apply to children who refuse food though well able to swallow. One nasal feed is often sufficient.

As a rule nasal feeding can be performed with a soft rubber tube, but occasionally a stiff tube is necessary. Generally the patient should be fed every four hours, but this must to a certain extent depend on the individual case. Milk, if necessary peptonised or as Benger's food, should be the chief ingredient Raw meat juice, eggs, cream, brandy (if ordered), or medicines may be added to the diet. The quantity in each meal must vary with the age, size, &c., of the patient About four ounces is often as much as a child of from three to five years old will be able to retain and to absorb Even this may have to be reduced. All foods should be strained, measured, and given warm. If vomiting occur it may be due to the amount or contents of the meal or to the frequency of administration. All these details can be variously modified. The amount may be diminished, the frequency lessened, or some constituent which is supposed to be the cause of vomiting altered or omitted. If, however, the vomiting persist rectal alimentation must be tried in lieu of nasal feeding It is worth noting that after the first few nasal feeds feeding by this method as a rule becomes remarkably easy owing to the effect of habit and in some cases to actual loss of sensation.

III.—RECTAL ALIMENTATION.

This should be resorted to when feeding by the mouth or nose fails or is insufficient. The following are the chief conditions where it is required: (1) vomiting; (2) great difficulty in passing the nasal tube from various causes; (3) when nasal feeding acts harmfully on the patient, owing to fright, struggling, or other cause; and (4) epistaxis caused by passage of the nasal tube

Rectal feeding should be performed by means of a funnel and soft rubber tube, passed as high up the rectum as possible, and the feed allowed to flow in by force of gravity. A ball syringe should not be used, for it is impossible to gauge accurately the amount of pressure used; experience also shows that nutrients given this way are not so well retained. The feeds should be given warm about every four hours They should be measured and strained. The amount of the feed should depend on the age, &c., of the patient. In young children it varies from two to four ounces and has to depend on the amount retained and absorbed. The feeds should have as their basis peptonised milk, and often this is their only constituent. Raw meat juice, white of eggs, and occasionally yolks of eggs are added. In some cases brandy is added and tolerated for a long continued period. Often, however, probably owing to its irritating the

TABLE SHOWING THE AMOUNT AND NATURE OF FOOD, &C., RETAINED (APPROXIMATELY) IN CASE 1.

Date.	By mouth.	Nasal feeding.	Rectal feeding.	Injections of horse serum.	Remarks.
Feb. 19th.	Milk,* 8 oz.; brandy, 2 drachms	—	—	—	Antitoxin, 18,000 units.

" 28th.		Peptonised milk, 16 oz.; cream, 3 oz; brandy, 1½ oz.	Peptonised milk, 24 oz.; water, 12 oz	—	Retched after the nasal feed; no vomiting.
" 29th		Peptonised milk, 16 oz.; cream, 3 oz.; brandy, 1½ oz.	Peptonised milk, 24 oz., water, 12 oz.	—	—
" 30th.	Five fingers of toast.	Peptonised milk, 16 oz.; cream, ¾ oz.; brandy, 1½ oz.	Peptonised milk, 24 oz., water, 12 oz.	—	—
May 1st.	Two fingers of toast.	Peptonised milk, 12+oz.; cream, 2¼ oz.; brandy, 1½ oz.	Peptonised milk, 20 oz.; water, 12 oz;	—	Two feeds omitted by rectum; part of one nasal feed vomited.
" 2nd.	Toast, 1 egg; mince and potatoes; Benger's food, 1 oz.	Peptonised milk, 12–oz.; cream, 3–oz.; brandy, 1½ oz.	Peptonised milk, 12 oz., water, 10 oz.	—	Rectal feeding omitted; one nasal feed omitted; vomited part of one nasal feed; vomited a little of dinner.

TABLE SHOWING THE AMOUNT AND NATURE OF FOOD, &c., RETAINED (APPROXIMATELY) IN CASE 1.—(*Continued*).

Date.	By mouth.	Nasal feeding.	Rectal feeding.	Injections of horse serum.	Remarks.
May 3rd.	Toast, bread and butter, 2 eggs, milk jelly, mince and potatoes.	Peptonised milk, 12 oz.; cream, 3 oz; brandy, 1½ oz.	—	—	Vomited part of one nasal feed.
„ 4th.	Bread and butter, fish and potatoes, 2 eggs.	Peptonised milk, 12 oz.; cream, ½ oz.; brandy, 1½ oz.	—	—	—
„ 5th.	Bread and-butter, fish and potatoes, 2 eggs.	Peptonised milk, 12 oz.; cream, 3 oz.; brandy, 1½ oz.	—	—	—
„ 6th.	Bread and butter, fish and potatoes, 2 eggs, milk pudding.	Peptonised milk, 12 oz.; cream, 3 oz; brandy, 1½ oz.	—	—	—
„ 7th.	Bread-and butter, fish and potatoes, 2 eggs, milk pudding.	Peptonised milk, 8 oz.; cream, 2 oz; brandy, 1 oz.	—	—	Vomited whilst one feed was given.
„ 8th.	Bread and-butter, fish and potatoes, 2 eggs, milk pudding.	Peptonised milk, 12 oz; cream, 3 oz.; brandy, 1½ oz.	—	—	—
„ 9th.	Bread-and butter, chicken and potatoes, 2 eggs, milk pudding.	Peptonised milk, 12 oz.: cream, 3 oz.	—	—	Brandy omitted from nasal feeds.
„ 10th.	Bread-and-butter, chicken and potatoes, 2 eggs, milk pudding.	Peptonised milk, 12 oz.; cream, 3 oz.	—	—	Vomited once.
„ 11th	Bread and-butter, chicken, milk pudding, 2 eggs, 4 milk biscuits.	Peptonised milk, 12 oz.; cream, 3 oz.	—	—	—
„ 12th.	Bread and-butter, chicken, milk pudding, 1 egg, 4 milk biscuits.	Peptonised milk, 12 oz.; cream, 3 oz.	—	—	
„ 13th.	Bread-and-butter, chicken, milk pudding, 2 eggs, 4 milk biscuits.	Peptonised milk, 12 oz.; cream, 3 oz.	—	—	Vomited part of dinner · great difficulty in swallowing fluids till this date.
„ 14th.	Diet the same and in addition 3 oz. of peptonised milk.	Peptonised milk, 12 oz.; cream, 3 oz.	—	—	—
„ 15th.	Diet the same and in addition 4 oz. of peptonised milk.	Peptonised milk, 12 oz.; cream, 3 oz.	—	—	—
„ 16th.	Diet the same and in addition 4 raw meat sandwiches	Peptonised milk, 12 oz.; cream, 3 oz.	—	—	—
„ 17th.	Milk, 1½ pints; cream, 1 oz.; chicken, biscuits; bread-and-butter; eggs; 6 raw meat sandwiches.	Peptonised milk, 12 oz; cream, 3 oz.	—	—	Vomited once.
„ 18th.	Milk 1½ pints; cream, 1 oz.; chicken; biscuits, bread-and-butter; 2 eggs; 6 raw meat sandwiches.	Peptonised milk, 12 oz.; cream, 3 oz.	—	—	Nasal feeding ordered to be omitted. The patient after the 18th soon got back to an ordinary but generous diet.

* The milk was diluted by addition of barley-water.
† Made from raw steak; 1 lb. allowed daily.
‡ One water feed omitted daily to allow bowel to be washed out.
§ Same amount of cream and brandy given in the 24 hours.

rectal mucous membrane, it is apt to set up diarrhœa. Sometimes it may be ordered to be given apart from the nutrient feeds and diluted with water when symptoms show themselves suggesting its use. The milk feeds should be preceded by water feeds of three or four ounces of warm water, given in the same manner as the milk feeds, about an hour before these feeds are given. Sometimes in addition to the milk-and-water feeds small nutrient suppositories may be given provided they are retained and absorbed. The bowel should be washed out every 24 hours and it is possible from this to get some idea as to whether the food given has been absorbed. I do not think large rectal feeds are advisable as they are apt to set up diarrhœa. Diarrhœa is a troublesome and serious complication in these cases, for rectal alimentation has to be depended on to support life over far longer periods than is usually supposed possible. Thus it is not uncommon for cases to be fed by the rectum alone for three weeks, and cases occur where rectal feeding has to be continued over four or five weeks and even seven weeks. If the feeds are not retained or only retained in part their amount should be diminished, or they should be given less frequently, or some part of the feed should be omitted—e g., brandy. Sometimes washing out the bowel and giving it a rest is useful. The water feeds may be badly retained; they also may have to be diminished in quantity or given less frequently. If these means fail, a starch or a starch-and-opium enema containing a few drops of tincture of opium will often be found useful. During the period of abstinence from food by the stomach patients have a great craving for food, often of the most varied kind. They are tried by mouth with water, raw meat-juice, peptonised milk in drachm doses. Occasionally, owing greatly to their craving, they are tried with a morsel of thin bread-and-butter, &c., but, as a rule, it is rejected by the stomach.

IV.—SUBCUTANEOUS INJECTIONS.

In addition to the above forms of administering food the injection of sterile horse serum into the subcutaneous tissues is to be recommended.[1] Dr. F. E. Laslett has also advocated saline infusions.[2] Horse serum should be used when the amount of nourishment taken by stomach or rectum, or both, appear to be insufficient to support life. Sometimes it is used as the only means of feeding patients owing to continued vomiting and diarrhœa. It should be injected into the loose subcutaneous tissues of the trunk. If given over a prolonged period, I think from 20 to 40 cubic centimetres are often as much as it is advisable to inject daily. As a rule, patients submit to its injection well and I have occasionally noticed that children have been injected without any untoward effect who have become cyanosed on attempting to nasal-feed. As far as I know the only indication against the use of these injections is hæmorrhage into the subcutaneous tissues adjoining the site of injection. I have, however, seen no dangerous effects from its use, either from these hæmorrhages or other causes. Transient rashes have occasionally been observed after its use. It is impossible to speak dogmatically as to its value, for in all cases, as far as possible, where it is given, nourishment is also introduced by other channels. However, if it is absorbed the patient has had so much added nourishment, and this is of great importance where one's resources are so taxed in feeding. Some nurses have thought that patients are more restful after the injections, and that in cases which are constantly retching and vomiting these symptoms have been less marked. My own impression is that the injections of horse serum have been beneficial.

[2] THE LANCET, Oct. 20th, 1900, p 1131.

CONCLUDING REMARKS.

Patients who have been fed by the rectum for some weeks become extremely emaciated and not infrequently develop petechial hæmorrhages, generally in the trunk, and they may be profuse. So far I have made little or no reference to drugs. My experience of most if not all as regards their action in the vomiting of diphtheria has been uniformly disappointing. I have spoken separately of the various modes of feeding. In practice, however, they are frequently combined. I am much indebted to the nurses, who have supplied me with careful notes, and whose advice in many practical details of the different methods of feeding has been of much value. I append notes of a few cases, one *in extenso*, specially with reference to their feeding.

CASE 1.—The patient, aged six years, was admitted to Brook Hospital on Feb. 19th, 1900, and was discharged on July 13th, 1900 The patient was admitted on the third day of the disease, with very severe faucial diphtheria. The heart was affected early. Epistaxis occurred on the fifth day. Albumin was seen from the seventh to the [illegible] commenced on the seventh [illegible] nasal voice, regurgitation, [illegible] paralysis, paralysis of deglu- [illegible] The accompanying table shows the approximate amount and nature of food, &c., retained.

CASE 2.—The patient, aged six years, was admitted to Brook Hospital on Sept. 14th, 1899, and was discharged on Feb. 8th, 1900. The patient was suffering from severe faucial diphtheria and was admitted on the third day of the disease. There were albuminuria, palatal paralysis, and diaphragmatic paralysis. Vomiting started on the fifteenth day and ceased about the forty-third day. 10 000 units of antitoxin were given on the third day of the disease, and 12 000 units of antitoxin were given on the fourth day of the disease. On the twelfth day, owing to retching, peptonised milk only was ordered by the mouth. On the sixteenth day rectal feeding alone was ordered. The feeds, consisting of four ounces of peptonised milk and half an ounce of brandy, were ordered to be given every four hours. In addition, water feeds of four ounces were ordered one hour before the milk feeds. On the seventeenth day milk enules (containing peptone from five drachms milk) were ordered four-hourly. On the twentieth day, owing to the feeds being badly retained, the brandy was omitted from each feed and the quantity of milk was reduced to three ounces. On the twenty-second day the milk feeds were further reduced to two and a half ounces each feed. At the same time only three water feeds were given in the 24 hours; but the milk enules were continued every four hours. These rectal feeds were continued till the thirty sixth day. On the twenty-ninth and thirtieth days a starch and opium enema was required. Twenty cubic centimetres of horse serum were injected on the twentieth, twenty-first, twenty-second, twenty-third, twenty-fourth, twenty-fifth, twenty-sixth, twenty-seventh, and twenty-eighth days. The last two gave rise to subcutaneous hæmorrhage. From the thirty-first to the thirty-sixth day the patient took a small but appreciable amount of food by the mouth. From the thirty-sixth to the fiftieth day the patient was nasal-fed, but each day had in addition by the mouth one or two eggs and some bread crumbs. After the fiftieth day the patient gradually got back to a normal diet.

CASE 3.—This patient, aged five years, was admitted to Brook Hospital on Nov. 8th, 1900, suffering from severe faucial diphtheria, it being the fifth day of the disease. Albuminuria was present from the time of admission to the thirty-third day. Vomiting commenced on the eighth day and did not cease entirely till the sixtieth day of the disease. Palatal paralysis was first noticed on the seventeenth day. 12,000 units of antitoxin were given on the fifth day and 12,000 units of antitoxin were given on the sixth day. Rectal feeds were ordered first on the twelfth day, consisting of three ounces of peptonised milk and half an ounce of brandy, given four-hourly. On the thirteenth day the milk was increased to four ounces each feed. On the nineteenth day the brandy was diminished to two ounces divided over the rectal feeds given in 24 hours. Three-ounce water feeds were also ordered one hour before the milk-and-brandy feeds. *The rectal feeds were omitted on the fifty-seventh* day. Nasal feeds, consisting of one ounce of peptonised milk, one drachm of raw meat juice, and one drachm of brandy, were first ordered four hourly on the fifty-fifth day. On the fifty-sixth day the milk was increased to two ounces each feed. On the fifty-seventh day the nasal feeds were increased to three ounces of peptonised milk, one drachm of meat juice, and three drachms of brandy. On the sixty-fourth day the patient began to feed by the mouth. On the seventy-second day the nasal feeds were increased to five ounces of peptonised milk; the brandy was omitted. These were given three times a day. On the eighty-first day they were omitted, and from that date the child gradually got back to an ordinary diet. From the twelfth to the fifty-fifth day the patient was fed almost entirely by the rectum. On the fifteenth, twenty-fourth, and thirty-ninth day 20 cubic centimetres of horse serum were injected as she was then retaining her feeds badly. The child had a great craving for food and was occasionally tried with it in minute quantities, but mostly it was rejected by vomiting, until the fifty-sixth day. On the thirty-sixth day one nasal feed was tried, but this was vomited, and for some days the vomiting was increased.

CASE 4.—The patient, aged five years, was admitted to Brook Hospital on Jan. 14th, 1899, suffering from faucial diphtheria and was discharged on June 1st, 1899. On June 16th there was vomiting. Peptonised milk was ordered and brandy one ounce in the 24 hours. On the 17th the vomiting stopped The patient then did well and was on a fish diet on Jan. 22nd and on child's diet on Feb. 3rd. On March 1st the child collapsed in the morning and vomiting occurred. Half an ounce of brandy was given by the rectum. Mouth feeding was omitted and the child was ordered four-hourly rectal feeds, each feed consisting of four ounces of peptonised milk and half an ounce of brandy. Water feeds of from three to four ounces were given one hour before the milk feeds. On March 2nd the yelk of half an egg was added to each milk feed. On the 25th there were punctiform hæmorrhages in the body. On April 3rd brandy only was given in alternate feeds. On the 4th the patient commenced to take food by the mouth for the first time since March 1st. On the 10th two rectal feeds were omitted On the 12th rectal feeds were omitted. In this case the child was fed by the rectum alone from March 1st to April 4th, a period of five weeks

Shooters Hill, Kent.

SCARLATINAL INFECTION: AN INQUIRY AND AN ILLUSTRATION.

BY J. B. PIKE, M.R.C.S. ENG., L.R.C.P. EDIN.

THE pathogenic germ of scarlet fever appears to require moisture for its development, and, this being the case, it seems somewhat strange that dry exfoliated epidermis should have received so much credit as the potential in scarlatinal infection. Latterly more attention has been paid to nasal discharge, and I believe pus from the middle ear is also suspected, This being granted the question arises, How long can these discharges convey specific scarlatinal infection? Can scarlet fever microbes lurk insidiously in hiding? Certainly the middle ear and mastoid cells form excellent quarters for the secret dwelling, if the germs can lie there quietly, without resentment of the tissues. If they can do so for a long or indefinite time we must enlarge our view of the infective period of scarlet fever. Isolation can hardly be indefinite, but if we recognise an ear discharge occurring even a year or more after scarlet fever as possibly or probably infectious something may be done to prevent the spread of the disease.

Another interesting question which is suggested by the following illustrative case is this, Is a secondary auto-infection possible from scarlatinal poison lurking in the cavities of the temporal bone? I cannot pretend by one case to answer these questions, but I think the following notes illustrate the inquiry, and subsequent observation may possibly throw more light upon the matter.

A girl, aged 14 years, was isolated, together with one of her sisters, for scarlet fever on Jan. 5th, 1898. She was about again on Feb. 24th and appeared to regain her normal health. On Sept. 27th, 1899, she was attacked by sore-throat followed by earache. I saw her first with regard to this illness on Oct. 14th, 1899, when she was suffering a good deal from the ear, a discharge having been noticed from the meatus for about a week. On Oct. 17th the ear was very troublesome and there was some puffiness over the mastoid. She was also showing symptoms of acute nephritis. It was arranged to make Wilde's incision the next day. On the 18th, however, an older sister developed scarlet fever, and this occurred without our being able to trace any outside infection. My patient was consequently moved to a private ward at the Loughborough Hospital and on the same day an incision was made. A superficial necrosis of the mastoid was found which was removed together with a part of the posterior wall of the meatus. The operation was made as short as possible as prolonged anæsthesia was undesirable with the acute kidney condition. In its subsequent progress the case gave rise to much anxiety. For some time there was high temperature, rising at night or early morning to from 103° to 105° F., and it was difficult to determine how much this was due to mastoid trouble and how much to nephritis. On this point I had the advantage of consultations with Mr. Bond of Leicester and Dr. Howarth of Derby, and the decision was not to interfere further with the mastoid unless there was an extension of local symptoms. Ultimately all symptoms of active mischief subsided, the incision healing and the urine becoming free from casts and albumin The patient went home convalescent on Dec. 6th, 1899.

The points illustrative of the previous inquiry are, first, the infection of the older sister, and secondly, the sore-throat followed by nephritis and associated with mastoid and middle-ear trouble, which had been for some time latent. Apart from these points the case is interesting as an example of nephritis associated with mastoid necrosis and simulating septicæmia.

Loughborough.

PURE UREA IN THE TREATMENT OF TUBERCULOSIS.

By HENRY HARPER, M.D. R U.I.

IN THE LANCET of March 9th, 1901, I was permitted to place on record my experience of pure urea in the treatment of tuberculosis. The subject is so vast, the problems in physiology are so great and many-sided, the whole matter is so closely connected with organo-therapy, and the possibilities are so far-reaching, that I once more venture to record my further experience of urea. I selected urea, a substance of known chemical composition, from amongst its congeners, the "great end-products of nitrogenous metabolism," as an antitoxin for the tubercle bacillus. Hitherto urea has been looked upon as a waste product of the body of no further use in the economy—in fact, just as coal-tar used to be previously to the discovery of the aniline dyes it was found to contain.

My opinion is that urea is a constructor or builder up when administered in tuberculosis. This view is forced upon me by the frequent expressions of patients stating that they feel so much improved since eating kidney, liver, or brain—all substances rich in urea—in conjunction with urea ingested by the mouth. A few chronic phthisical patients have stated that these substances acted like a stimulant on them. Urea props up and holds together the tuberculous subject better than any other substance with which I am acquainted.

From my investigations among many families subject to gout and its allied diseases, including all forms of calculi except phosphatic, I am persuaded there is antagonism between these diseases and tuberculosis, and that this class of patients possesses a natural antitoxin against the bacillus. Here it is worthy of note that nuclein, which is used as a remedy in tuberculosis, in certain blood diseases accompanied by leucocytosis splits up and forms uric acid. "The discovery of the linking-on of toxin to proteid bodies and the assimilation by the cells, with the consequent appearance of anti-bodies, was one of the most remarkable contributions to the knowledge of immunity that had yet been made."[1] "A molecule of proteid, hitherto dead, coming within the grasp of the molecular forces of the living substance, is caught up by it and, as we phrase it, made alive."[2] Probably this is how urea acts when ingested by the tuberculous.

CASE 1.—A man, aged 25 years, a tailor, came under my care on Dec. 21st, 1900. He had been very ill for 10 months with cough, sputum, loss of flesh (1½ stones), and night sweats; his evening temperature was 101·5° F. There was much dyspnœa on exertion and he had a poor appetite. No hæmoptysis was present. The patient looked very thin and far advanced in phthisis. Physical examination revealed much damage to the right lung; percussion was dull; there were loud crackling sounds denoting rapid softening of the upper half of this organ; the sputum contained many bacilli; the prognosis was very unfavourable. The grave nature of his disease was explained to the patient and his aid was besought in carrying out the treatment. He was ordered to live outdoors nearly all the day and to eat four good meals daily, each meal containing plenty of animal food. He ate daily one well-cooked kidney or an equal weight of liver, calf's or sheep's brain. He was told that these things were given to him as a medicine and he took them willingly. Along with this pure urea in 20-grain doses four times daily in separate mixture was taken. After meals a mixture of hydrochloric acid, strychnia, and pepsine was taken as well to aid digestion; also half an ounce of cod-liver oil daily with breakfast. The patient soon expressed himself feeling better, gaining weight and strength, the cough and sputum lessening Now he says he is quite well, his weight being only four pounds below what it was at the begining of his illness. The sputum still contains bacilli.

CASE 2—A man, aged 38 years, came under my care on Feb. 28th, 1900. For many years he had been a carter. During the last three years he had kept a public-house and for a number of years had been a big beer-drinker. Two years previously his health began to fail, as manifested by repeated "bilious bouts." Slowly, shortness of breath and cough came on with rapid loss of flesh. He had several attacks of pulmonary hæmorrhage. When first seen by me he had been confined to his bed for 16 weeks, being nursed up in a warm room and afraid to have the door opened. He had all the appearance of long-standing wasting disease, including the clubbed finger nails. There were daily hectic, anorexia, and very frequent cough, with much sputum crowded with bacilli. The physical signs revealed a cavity at the left apex with loud cavernous râles and fine crepitation at the margin of infiltration with the sound lung. The heart sounds were feeble; the liver was distinctly enlarged. The patient was ordered out of bed and changed his room during the day. He was put on a light nutritious diet, including milk, fish, and mutton. A mixture of hydrochloric acid and strychnia, with pepsine, was taken after meals, the same as in Case 1; 20 grains of pure urea dissolved in water with half-minim doses of creasote in combination were taken soon after food thrice daily. On this treatment the patient soon showed improvement. Less cough and better appetite followed within a week; two weeks later he was able to go out for carriage drives. On April 1st he was able to walk freely and he had gained four pounds in weight. From this time onward improvement was more rapid. With the view of increasing the urea in the food ingested he ate daily one well-cooked kidney or an equal bulk of liver or brain-substance. The importance of these things as a medicine for his disease was explained to him and he ate them willingly. He has recovered so much that he is able to do work, including grooming his own horse, and drives about freely now. His worst trouble is dyspnœa on exertion. He has very little cough or sputum. Bacilli are sometimes present, more frequently absent.

CASE 3.—A man, aged 51 years, a stonemason, came under my care on June 20th, 1900. He had not been strong for several years and had been ailing 18 months with "bad cold," but was not laid up in bed; increased cough and more sputum followed. Since Christmas he had become much worse with more cough and dyspnœa. He had several attacks of hæmoptysis and marked laryngitis for one month; he had lost 1 stone in weight during the last six months. On examination the patient presented all the symptoms of stonemason's phthisis; he had a thin, wasted body with bad thoracic movements, hyper-resonance over the lungs, except at the right apex which revealed a cavity with marked metallic tinkling on deep inspiration. There were signs of many foci of tuberculosis in both lungs, areas of fine crepitation with coarse rough râles all scattered over. The sputum was full of peculiar short stumpy bacilli. A diagnosis of pulmonary and laryngeal tuberculosis was made The prognosis was grave

---

[1] Brit. Med. Jour., March 16th, 1901.

[2] Stewart's Physiology.

The treatment consisted of the following. He was put on very nutritious food; as much fresh butcher's meat as possible was consumed, with eggs, milk, cream, and one good portion of well-cooked green vegetables daily. One kidney well cooked or an equal weight of fresh liver daily was consumed with some one of the meals, usually the breakfast He lived in the open country in the hilly part of *Derbyshire and spent his time almost entirely out of doors.* He practised with light dumb-bells every day and did some light gardening. 20 grains of pure urea dissolved in water with half-minim doses of creasote suspended in a little mucilage were administered four times daily after the principal meals; also one ounce three times a day of the following mixture: 24 grains of sulphate of iron, 30 grains of carbonate of potassium, one and a half drachms of powdered myrrh, one and a half drachms of powdered glycyrrhiza, 12 minims of creasote, and water to 12 ounces were the medicines ordered. "Perfected" cod-liver oil or bynol was taken fairly regularly once a day with the food. The patient slowly but steadily improved, from the first gaining strength and suffering less; now he has regained his weight The laryngitis is almost gone. There is very little cough or sputum; the latter still contains bacilli. Except for dyspnœa he considers himself fairly well.

CASE 4 —*A boy, aged 16 years, employed at the telephone* office, came under my notice on Nov. 11th, 1900. There was no history of tuberculosis in the family. He had been ill for two months He was weak, losing flesh, and easily getting colds; during the last three weeks he had been much worse, with feverishness, night sweats, an evening temperature of 101 5° F., loss of flesh, very marked dyspnœa, and no hæmoptysis. A large quantity of yellow sputum was expectorated every morning which showed bacillus in abundance. The diagnosis of tuberculosis of the right base of the lung was made. The boy was sent into the country and ordered to eat plenty of all kinds of animal food, including kidney, liver, and brain. He spent the greatest portion of the day out-of-doors, knocking about actively, doing cycling, a little football, and dumb-bell exercise. 20 grains of urea, four times daily, with compound mixture of iron as above in separate mixture and a tablespoonful of cod-liver oil taken with breakfast comprised his whole treatment. On Jan. 20th, 1901, he had gained four pounds in weight, his cough had almost gone, and there was very little expectoration. From this time onward improvement was very marked, the cough and sputum ceasing entirely, the physical signs of lung disease gradually removing, so that now (June, 1901) it takes very careful auscultation to detect the difference in the two bases Apparently the boy is quite well. There is no rise of temperature or any other sign denoting latent tuberculosis at work. *He has* gained ten pounds weight in all.

CASE 5.—A married woman, aged 36 years, came under my care on August 20th, 1900. She had been ailing for five months; tuberculosis started from nursing her father-in-law in severe illness and loss of sleep The disease was ushered in with hæmoptysis, of which she had several attacks during the first week. Two months later she had a return, the same as before. One month previously to being seen by me she had another attack, much the same as the first. On first examination she complained of weakness and loss of flesh; she had lost six pounds in one month; there were dyspnœa, cough, and expectoration; the sputum was teeming with bacilli. There were much crackle and symptoms of softening of the right apex in the supra-clavicular region, involving the upper third of this lung. This patient had a peculiar, shiny, scaly skin, with the hands and face cracked and tending to bleed, and slowness of speech consequent on imperfect thyroid function.

Had it not been for the tuberculosis I would have administered thyroid gland for this skin trouble as I had done with success in cases of skin disease like this. But I had always looked upon the thyroid gland as a substance with disintegrating effect on the organism when ingested. This opinion was forced on me by having seen a woman drop from 18 to 14 stones in weight within 18 months on a selected diet with alkali and thyroid gland taken internally. In my experience of tuberculosis I have never seen any good follow from using reducing agents, such as mercury, iodine, or alkalies. Here I was not called upon to treat the skin primarily, but soon after the ingestion of urea and kidney by the mouth the skin disease vanished. This patient told me repeatedly how much good she derived from these substances —that they acted like a stimulant.

The patient was put on a liberal diet, rich in animal food, and sent into the country for two months for a change of air. She took plenty of exercise out of doors and felt cheerful and hopeful of improvement. She was put on compound mixture of iron with minim doses of creasote added; bynol fitted in with her principal meals; pure urea in scruple doses three times daily was her treatment. There has not been *any return of hæmorrhage. The patient improved from the* first, eating more food and gaining strength and weight She is now 10 pounds heavier than last August. This treatment has been a fairly perfect remedy for the pulmonary tuberculosis as well as curing the skin disease. She is gaining flesh and feeling well The sputum is now free from bacilli. The woman considers herself cured.

To me this case has special interest, as I have notes of three cases of myxœdema in women where I have attended in the same family more than one child with tuberculosis. Now, if we put the threads together of a case like this and bring to bear on it the light of experimental physiology it seems to me it leads us to conclusions of great importance. Thyroidectomy performed on carnivora is followed by death usually in a few days The same operation performed on herbivora is not followed by death. For instance, rabbits can live as well after as before the operation We know that *carnivora are more immune to tuberculosis than are rabbits.* The above facts seem to point to antagonism between thyroid gland and tuberculosis. On the other hand, families with imperfect thyroid function are liable to tuberculosis. Here it is worthy of note that thyroidin increases urea

Personally I have no fear of contagion in tuberculosis. I have formed this opinion after handling a considerable amount of the different forms of this disease during the last 17 years. I am constrained to make this statement because the terror of contagion is rife, so much so that one might think we had to deal with a disease as contagious as plague, enteric fever, or scarlet fever, whereas it is nothing of the kind. For instance, quite recently I was called in to see a patient with a mild attack of influenza. His wife had been in the habit of taking dainties to a consumptive in the very advanced stage of this disease. My patient had visited this man one week previously to my seeing him. When I first saw the patient he would insist that he had "caught" tuberculosis from the man he had visited. Further, he refused to use my clinical thermometer under the tongue, although he saw it washed in his presence. He must use his own new thermometer. This is terror of contagion with a vengeance The proverbial red herring in the form of dread of contagion has been drawn across the track, and is diverting medical thought from the path of true progress, which will be found to lie in a more careful study of the clinical history of the disease. In my cases of apparent contagion, such as husband and wife, there seemed to be a common cause at work—unhealthy home, following unhealthy occupations, or eating unsuitable food

Every practitioner who meets a case of tuberculosis needs to have it printed in letters of gold in his mind, that the disease is caused by a feeble microbe belonging to the vegetable kingdom, that it has taken up its position there in the human body by accident, that being a vegetable substance its natural habitat is not the animal tissues, and that his first thought should be to make things so uncomfortable for the intruder that it must cease its existence This can be done by slightly altering the toxicity of the tissues and fluids. This epitomises my opinion of the value of urea in tuberculosis A large number of the population possess a natural antitoxin against the bacillus; a smaller number are lacking in this In some that possess the natural antitoxin susceptibility can be acquired by unnatural or unhealthy surroundings, such as back-to back houses, always charged with CO_2, and badly ventilated workshops In persons leading unnatural lives, like dressmakers and needle-women who seldom taste animal food and subsist largely on weak tea and bread, here anabolism and katabolism are reduced to a minimum. The functions of the body are performed lazily. What I believe to be the natural antitoxins—urea, uric acid, kreatin, xanthin, sarkin, and guanin—are reduced accordingly. Deficient oxygenation within the tissues and stagnation by reason of CO_2 is the result. I believe the retention of the latter to be very conducive to the growth of the bacillus. This impression is formed from the peculiar sweetish carbonic acid odour, like that of a crowded room, I have noticed in these back-to-back houses.

Biology tells us that the bacillus is a vegetable micro-organism and if we study its cultivation bacteriologically we find it very interesting indeed. There is one cardinal principle and that is that a vegetable substance must be present in any medium selected to cultivate the microbe, the favourable being potato, agar-agar, and glycerine with meat broth. To my mind the bacteriological cultivation of the bacillus is suggestive of an explanation why a large number of herbivora are so susceptible to the tubercle bacillus. Most likely the blood and fluids within these animals contain just enough saccharine matter to provide a pabulum for the bacillus to grow in. The blood of carnivora being immune is deficient in this. Place side by side with this the acknowledged fact that excessive ingestion of starchy and saccharine food causes diabetes, and clinically that the diabetic fluids are a happy hunting ground for the bacillus, and it affords room for deep reflection in regard to both the causation and the prevention of tuberculosis. Contagion and prevention, which at present seem to monopolise public attention, are but two links out of a long chain of considerations respecting the ubiquitous tuberculosis. The problem of contagion and its corollary prevention is only partly solved by the discovery that a syringeful of dirt (bacilli are only this) injected into an animal sets up tuberculosis, and not even the support this receives from our being able to cultivate the bacilli outside the body settles this question. To-day we need to take the advice given in *Hamlet:* "By indirections find directions out."

The bacillus is no new creation. I have no doubt it was floating about in the garden with Adam. Phthisis was known to Hippocrates 460 years B.C. The prevention of tuberculosis begins, not with the bacillus, but with the crowding together of human beings in insanitary conditions lowering the vitality. Increase in the death-rate of tuberculosis goes hand-in-hand with crowding. The reason that the bacillus has assumed such importance is not from its deadly nature in itself, but that human tissue has been so transformed through civilisation and town life that the bacillus finds a suitable soil for its secret operation. This statement is borne out by the fact that in rural districts the death-rate from phthisis stands the same to-day as 50 years ago. This does not look like active contagion. It seems to me that it is time we viewed the disease in the light of modern physiology, and that now, after 19 years of fighting with the bacillus, we changed the scene of action and looked to the cell-units and the fluids which surround them—the bricks and mortar of the building—to try to discover the natural antitoxin. It is in the energies of the cell and the subtle juice that bathes it in the healthy state that the bacilli meet a foe clad in an iron armour which their missiles fail to penetrate. This explains why the healthy can live half, or even the whole, of their lives in dens of contagion and keep immune. Of course, viewed in this light, to tackle tuberculosis we must go to the fountain of mischief and acknowledge at once that it is the outcome of civilised life. The bacillus finds its favourite prey among those dwellers in cities who feel hardest the struggle for existence. We know that a man who follows a quiet, sedentary occupation consumes far less food than a man who does hard muscular work or leads an active, energetic life; we know also that the nitrogenous material excreted by the kidneys rises and falls with the amount of proteid consumed. Now if we apply this well-established truth in physiology to the patients who come before us with tuberculosis we shall see that it goes a long way to explain how those who follow sedentary lives, spending much of their time in vitiated atmosphere, fall a prey to the bacillus. I am referring now to town-dwellers. Here the intake and output are reduced to a minimum; the quantity of food consumed, meats especially, fall far below the standard needed for a physiologically healthy person; oxygenation in tissues and the elimination of CO_2 fall in the same ratio. The natural antitoxin which, I believe, belongs to the last extracts of animal food, of which extracts urea is the best-known representative in this chemical family, is too much diluted to arrest the bacillus at the moment of its entry. Once the bacillus takes up its abode in the human body we know how hard it is to dislodge. In the battle with tuberculosis the bacillus must be attacked from behind. It seems to me high time we gave up fighting the enemy by frontal attacks; and just as in the campaign now drawing to a close flanking resulted in success, so I think the principle should be applied to tuberculosis. Up to now frontal attacks have been the favourite, from burning brimstone, corrosive sublimate, carbolic acid, iodine, creasote, and, latest of all, formalin, to by-forms of these—*e.g.*, carbonate of guaiacol, benzosol, &c. We must flank the enemy by fixing our attention on the animal fluids, the common battle-ground. We have proof that there is a natural antitoxin for tuberculosis in both the human race and lower animals as well. Had it not been for this the human race would have been extinct ere now. Attention needs to be fixed on this; herein lies the prospect of advance. Bacteriologically the bacillus is a very feeble microbe, difficult to cultivate, a very trifling change in its environments being sufficient to arrest its growth—*e.g.*, change of air or food or occupation, or even a medicine rubbed into the skin of the abdomen for peritoneal tuberculosis. Connected with this is the fact that unless the bacilli possess a certain degree of the toxicity of their own products they cannot survive in the tissues of an animal, but are destroyed by the anti-bacterial properties of the tissues and fluids. By nature the cat is immune, but through long generations of domesticity in some instances it has become tuberculous, probably from being fed on milk, bread, and farinacea. This is a good example of an immune animal becoming susceptible. The underlying principle here applies to a large number of human beings whose food is physiologically wrong and who lead insanitary lives. We get good examples of this in the following classes. On looking over my cases these are the occupations that head the list of tuberculosis: clerks, warehousemen, lacemakers, framework-knitters, card-punchers, bobbin and carriage makers, lace-jenniers, lace-menders, clippers, machinists, cigar-makers, dressmakers, and needlewomen. In all these individuals the living machine works at less than half-steam pressure. Human beings are converted into money-making machines from stern necessity to earn their bread. They are like the horse on the bit—they cannot help themselves. This is a social problem urgently needing the nation's attention. I refer to town-dwellers.

If there is one thing above another that calls for the exertions of the National Association for the Prevention of Consumption, it is to distribute information relative to the very early beginnings of tuberculosis; also to inaugurate a system of voluntary examination of the apparently healthy who follow such occupations as the above, in order to anticipate tuberculosis rather than to let the disease get such a hold that treatment is of no avail. More good will result from this than from notifying the disease when "the man in the street" can tell what is amiss with the patient. Every practitioner has to lament that so many cases come to him too late for cure. No wonder the bacillus finds a happy home in these people. Their natural protection, the antitoxin, is destroyed or diluted to the vanishing point. The majority of these are cases of what I call "acquired susceptibility," and, I would add, are the most curable. In their standard of living their food is less than it should be by one-half, butcher's meat by two-thirds. The function of the cell-unit is practically in abeyance. The heart-beats and pulse are lessened from want of activity, the blood-stream that brings renewal and carries away effete matter in the healthy here doing its work lazily.

That rapid filling and emptying of the liver—the factory for turning out urea—is reduced in proportion; those rapid chemical changes associated with vital function are checked. In all these persons the fuel taken in to heat the furnace to keep the wheels of life moving is insufficient. One could write a prescription: half the number of hours of work, twice the quantity of food, animal food especially, consumed, four times as much exercise and fresh air, probably would prevent or would cure 50 per cent. of these cases. But the difficulty would be in dispensing this prescription. For years I have been struck with the low specific gravity and deficiency of solids in the urine of this class of patients; or in a few cases where the specific gravity is high this is from phosphates, which always denotes malnutrition.

In contrast with these I take the collier who I find very rarely suffers from tuberculosis, which seems remarkable from the dusty nature of his employment In colliers, for every single case of tuberculosis I see more than 30 with gastric disease In this class the intake and output of the organism are increased to the maximum and every living cell within the body is urged to do duty. Anabolism and katabolism have full play, imparting to the fluids such a degree of toxicity that it arrests the bacillus at the moment of entrance If one reviews the literature of the last 10 years on tuberculosis there is found a great effort to explain the mystery of suitable soil and unsuitable soil for the growth of the bacillus I think that Maragliano's serum most nearly unravels the mystery, but the great barrier to success with an agent like this is the difficulty in saturating the patient and maintaining this point of saturation sufficiently long to effect cure. I have notes of 11 families who are what I call typical cases of hereditary tuberculosis In these the lowest number of deaths per family is five; the highest is eight. I have selected these as exhibiting the most virulent form of the disease and the most incurable that the practitioner meets. In the majority of these cases I have tried all the known remedies, including mountain and country air, several patients making voyages to the Antipodes and residing there for a time A few have improved by the change, such as one patient who gained 40 pounds in weight by a residence of six months in Egypt but died one year afterwards Another spent two years in the hills behind Christchurch, New Zealand, but died 15 months after coming home. In nearly all these cases the treatment has been constructive, including fresh air, change of air, and abundant exercise The disease was approached by both frontal and flanking manœuvres in the form of drugs without avail. These cases are as truly hereditary as those of *diabetes, where a whole family succumbs to this disease* Still, I am sanguine enough to hope to see the time when we shall be able to apply a test to distinguish the susceptible from the immune

We have no remedy for cases like this until we discover an antitoxin. To me the point of interest in families like these is that some members are living and have remained well in [illegible] re standing as living [illegible] dividuals can live one [illegible] e bacilli and keep fr [illegible] the following that I have based this opinion 16 years ago I attended a man, aged 35 years, for destructive tuberculosis; he died within a few months. He left a wife and six little girls At various intervals since then four of these girls have been carried away I am now attending one of the remaining girls, ill with acute tuberculosis The mother nursed her husband and all the children with her own hands and yet remains in the best of health 18 months after her husband's death she married again; her husband also keeps healthy Further, there are three children by the second husband—the eldest being 11 years old the youngest [illegible] deformity of the thorax I tapped the father three years ago for acute pleurisy of the left side and now that lung is softening with tuberculosis 12 years ago the father married again and his second wife remains well, a picture of good health, yet she has nursed four of the diseased children, whose illness extended over four years in all, and has lived in such a nest of contagion. In another family where five sons died from virulent tuberculosis the mother nursed them all during a period of 17 years, yet she remains in good health, free from tuberculosis Surely this woman must possess a natural antitoxin to resist such inoculation.

It is surprising how people following such an unhealthy occupation as that of dustmen or tubmen, going about collecting night-soil, &c., who are inhaling bacilli probably every time the dust rises from emptying the tub, yet largely escape tuberculosis My explanation is that they are healthy men, much out of doors in all weather and good *feeders, and that the body is always well* charged with the end products of animal food, which acts as an antitoxin

Again, one comes across cases like the following which seem a paradox For many years I have attended a woman with typical winter-cough who is a dealer in old clothes and presumably inhales bacilli daily into her diseased bronchial tubes, where one would expect them to find a favourable soil for growth; and yet she keeps free from tuberculosis! I have examined her sputum several times with curiosity and always found it free from bacilli The following is another case A man, 50 years of age, a marine store dealer, who suffers from winter cough and who is inhaling daily the vilest dust loaded with all conceivable forms of bacteria, yet keeps free from tuberculosis Surely there must be a natural antitoxin here to arrest the bacilli at the moment of entrance

There is proof that alcohol lessens the production of urea in the liver; and when we remember that alcohol is carried almost direct to the liver, injuring the urea factory, this may explain why so many alcoholics lapse into tuberculosis Add to this the fact that there is such a large quantity of saccharine material circulating in the blood and diminished oxygenation in the lungs from weak heart, and in large beer-drinkers dilatation of this organ At present I have a good example of this in a publican [illegible] culosis and diabetes Weekly I t [illegible] yeast Before fermentation the [illegible], afterwards it is as low as from 1005 to 1010; urea 0 09 per cent Can we wonder that the bacilli find a home in these fluids?

Notwithstanding high authority to the contrary I believe there is antagonism between gastric ulcer and tuberculosis. *I base this statement on 400 cases of bleeding gastric ulcer.* I can find notes of only seven of these cases with gastric hæmorrhage and tuberculosis combined, being less than 2 per cent. Both diseases have a common cause, abounding most amongst those who follow sedentary and insanitary occupations, and both diseases are always preceded by anæmia, and dyspnœa is an early leading symptom. Take, for instance, *a number of machinists all working side by side* They have not long followed the work before anæmia manifests itself. One lot slide into gastric ulcer and another into pulmonary tuberculosis So far as the bacillus is concerned all have been exposed to a common danger—viz, this microbe floating in the air of the factory and all inhaling it alike Why this natural selection of the bacillus by one lot and not by the other? My reply is that these [illegible] predominant disease

It is a matter of every day observation that if a tuberculous woman becomes pregnant the tuberculosis becomes quiescent during the term of pregnancy, but immediately parturition takes place the bacilli become active I cannot remember signing a death-certificate of a tuberculous woman during pregnancy, although I have notes of 15 cases where the woman died from tuberculosis within nine months after parturition. In these cases there is evidently some antitoxin to the bacilli elaborated in the organism when in the pregnant state If we follow up this conclusion and consider the disease of pregnancy, puerperal eclampsia, which is caused by toxic substances of excrementitious matter circulating in the blood, which matter the excretory organs, notably the kidneys, fail to eliminate, this brings us into close quarters with the antitoxins which hold the bacilli in check during pregnancy, and that is the nitrogenous waste-products that abound plentifully both in pregnancy and eclampsia The nearest illustration that I can give of the value of urea in bad cases of tuberculosis is that it holds the disease in check—a check similar to that we see in pregnancy

The now well recognised fact that so long as pleurisy fluid remains in the thorax the activity of the bacilli is kept in check, but immediately the fluid is withdrawn the bacilli become active, suggests anti bacterial properties in this fluid; and when we remember that the pleurisy fluid is rich in albumin and contains urea, uric acid, xanthin leucin, &c, probably here urea plays the most important part as a bactericidal agent

Nottingham

NEW HOSPITAL NEAR BRISTOL.—At the meeting of the Kingswood (*Bristol*) *Urban Council held on June 5th* the chairman stated that under the provisions of the late Mr. Handel Cossham's will a general hospital will be erected at Kingswood The building, which is estimated to cost about £25,000, will shortly be commenced.

SULPHUR IN THE TREATMENT OF DYSENTERY.

BY G. E. RICHMOND, B.A., B.SC., M.B., B.S. LOND.,
LATE OF THE IMPERIAL YEOMANRY HOSPITAL, DEELFONTEIN, SOUTH AFRICA.

DURING my experience of the treatment of dysentery it seemed that none of the recognised methods were infallible. In giving sulphate of magnesia or sulphate of sodium it was of the utmost importance that the case should have come under treatment early in the attack, before much ulceration had taken place, as otherwise the septic absorption continued and in some cases little or no improvement occurred and the patient died in a condition of toxæmia with rapid failing pulse, delirium, and profuse diarrhœa, with much painful tenesmus The cases most suitable for this line of treatment seemed to be young adults of robust constitution. In giving ipecacuanha preceded by tincture of opium it was necessary to keep the patient in bed and almost to starve him whilst the administration of the drug continued to prevent the obstinate retching, which was otherwise certain to follow unless these precautions were taken, and which sometimes occurred despite all the care that was taken to prevent it. In such cases the misery of the patient racked with pain and worried with constant diarrhœa was greatly increased, and in scarcely a single case did the patient allow that his condition was ameliorated under 24 hours from the commencement of the treatment. Then in many cases, but not all, the diarrhœa became less, the tenesmus became much less painful, and the pulse, temperature, and general condition of the patient became much more satisfactory. Personally, before trying sulphur I came to the conclusion that Sir William Gull was correct when he summarised the treatment of dysentery in the three words, "rest, warmth, and ipecacuanha."

Tinc. Monsoniæ, combined with tincture of opium, was tried with pleasing results in some cases in which large quantities of blood were being passed and in some other cases where the dysentery had become more or less chronic, whilst in other cases, apparently quite similar, it was absolutely useless. Three minims of izal, combined with 20 grains of subnitrate of bismuth and from five to 10 minims of chlorodyne, was a useful prescription in many cases, and in most chronic cases bismuth and opium were prescribed for long periods with more or less success. Injections with boric acid, copper sulphate, and silver nitrate were frequently given in cases of obstinate ulceration and are undoubtedly of great service if the ulceration is situated in the rectum or the lower part of the colon, but can only be of slight service if the ulceration attacks the cæcum, ascending and transverse colon. Instead of izal I found that three minims of carbolic acid substituted in the prescription above were more reliable in action, and although many patients were taking 18 minims of carbolic acid per diem not a single case of carboluria occurred, although the urine was carefully watched in each case for this.

As none of these methods seemed perfect and as I was frequently coming across cases where it was desirable to change the treatment even more than once I thought that perhaps sulphur might be as useful in the treatment of dysentery as it had been found in the local treatment of anthrax in the place of ipecacuanha. I therefore prescribed 20 grains of sublimed sulphur combined with five grains of Dover's powder to be given four-hourly; the following are two of the cases in which this treatment was tried.

CASE 1.—Private ——, aged 34 years, was admitted into the Imperial Yeomanry Hospital, Deelfontein, on March 18th with dysentery. On admission the patient had been ill with dysentery for 11 days, having passed blood from the commencement of the attack. At first the amount of blood was slight, but latterly the motions had consisted of nothing but blood and mucus. For the last three or four days before admission he had been up all day and night with diarrhœa, passing nothing but blood and mucus. The bowels had been opened from 20 to 30 times or more in 24 hours. The pain in the abdomen was severe and straining was very distressing. The night before admission the bowels had been moved seven times; the motions contained no fæcal matter but consisted of blood and mucus and were small in amount. The temperature was 100·4° F., the pulse was 96, and the respirations were 20. The abdomen was distended and there was an area of acute pain and tenderness in the left iliac region with less severe pain over the whole of the left side. The abdomen was slightly rigid and did not move well with respiration. Palpation and even the slightest percussion caused acute pain over the iliac region. There was no vomiting but hiccoughs were present. The sulphur powders with Dover's powder were ordered on admission every four hours with belladonna fomentations to the abdomen. The next morning the temperature rose to 103·4°, the pulse was 100, and the respirations were normal, but the patient expressed himself as much more comfortable and better in every way. The abdominal condition was about the same as on admission. The bowels had been opened five times during the night and seven times during the day. Blood and mucus were still passed. The tongue was dry and covered with brown fur. On March 20th the abdomen was still very tender, but the pain was much less acute and the area of tenderness had greatly diminished, and palpation and percussion were easily borne. The straining was much less. The temperature fell to 99° at 6 P.M. The pulse was 84. The patient was still passing blood, but the motions were becoming fæcal. The bowels had been opened seven times in the 24 hours. On the 21st there was scarcely any pain in the abdomen and the tenderness had almost gone. The straining was improving. The motions were semi-solid and fæcal. No blood or mucus was noticed. The temperature was 98·2°. The tongue was clean and moist. After this the patient made an uninterrupted recovery. On the 25th the powders were given three times a day, the bowels being opened only twice in the previous 24 hours, and on the 26th one powder was ordered every night. On April 1st the patient was taking convalescent diet; he had no diarrhœa and was anxious to rejoin his regiment.

In this case severe dysentery had existed for 11 days before admission and from the abdominal condition there was evidently severe ulceration present, which no doubt gave rise to the temperature of 103·4° on March 19th, the day after admission. Plain milk was given on account of the abdominal condition, although farinaceous food as a rule seems to suit dysentery better than milk. From the very commencement of the treatment the patient became more comfortable, which is not the case with patients who are given sulphate of magnesia or ipecacuanha, who seldom own to any improvement in their general condition under 24 hours. It is also evident that the recovery was a rapid one, as in two days the motions had become fæcal and the diarrhœa was reduced to seven times in the 24 hours, and in eight days the patient had to be given an enema and was taking only one powder every night.

CASE 2.—Corporal —— was admitted to hospital on March 4th. He had been suffering from dysentery for five weeks. The bowels had been opened three times the previous night and 10 times in the hospital on the morning of admission. He had not passed any blood on the 4th, but was still passing mucus. The motions contained no fæcal matter. Tenesmus was troublesome. The abdominal pain was severe. Five grains of Dover's powder and 20 grains of sublimed sulphur every four hours were ordered about noon. On the 5th the bowels had only been opened once since the powders were given. The abdominal pain and tenesmus were much better. The patient felt much better and was much more comfortable. On the 6th the bowels had not been opened at all since the previous morning. The patient said that he felt "first-class." The powders were ordered three times a day. On the 8th the motions were fæcal and formed and rather constipated. The powders were omitted. On the 11th chicken was given and no diarrhœa occurred. On the 13th the patient requested to be sent to his regiment but was retained in hospital to recruit his strength and to see that no relapse occurred.

Here a very obstinate case of dysentery, which had lasted for five weeks, was cured immediately by the administration of sulphur and Dover's powders, and after recovery showed no sign of relapsing. In all of the cases that have been treated with sulphur the recovery has been rapid and the patient has seemed to derive relief more speedily from his pain and straining than with other methods of treatment. The cure with sulphur seems to be more certain and stable, as chronic conditions and relapses have not occurred, although with other remedies they have been prone to occur or the case has taken on a chronic condition. Blood and mucus are easily stopped and the motions quickly become fæcal. In some cases the number of motions per diem did not at once diminish, but the pain and straining were lessened and the character of the motions became more fæcal and contained little or no blood, and I was encouraged to continue the treatment because the patient's general condition was so much better.

I do not claim that sulphur is the one and only cure for dysentery, but I think it will be found a valuable addition to our stock of remedies for this most distressing complaint. Others may find cases which may resist its curative powers. At present I have not found one, nor have I found a single case relapse or become chronic, but I was not able to test it in a sufficiently large number of cases. As soon as the diarrhœa becomes less it is advisable to give the powders less frequently, otherwise obstinate constipation is the result. In some cases I have continued the sulphur treatment by giving half a drachm of the powdered sulphur every night alone. It does not, as a rule, give rise to much trouble from flatulence and tends to diminish the unpleasant smell of the stools. The sulphur seems to act as a strong antiseptic and to bring about a speedy healing of any ulcerated surfaces in the intestine. The amœba was carefully searched for in many cases of dysentery at Deelfontein but was never once found. It was searched for in all the cases which were treated with sulphur but was never found.

THE PRACTICAL CHOICE OF CLIMATE IN PHTHISIS.[1]

BY W. GORDON, M.A., M.D. CANTAB., M.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL DEVON AND EXETER HOSPITAL.

To determine the best place of residence for a patient who is suffering from phthisis is frequently a matter of some difficulty. The differences in type, stage, and complexity of the disease, the differences in individuality of those who are attacked by it, their different ages, their different circumstances, and the great number of places recommended, both at home and abroad, with their different reputations resting on different degrees of merit, have combined to make the question both difficult and obscure. The accumulation of experience and its embodiment in statistics have lately done much to lessen uncertainty. Much has been written and with admirable straightforwardness, but published statistics and precise judgments are almost confined to climates outside England. Consequently, whilst resorts of known value are available for the wealthy, we are rather at a loss in our treatment of the poor, which must be carried out at home.

On the whole, be the reason what it may, there is probably no subject in the whole range of medicine which is at once so generally important and so generally unknown as medical climatology. It may therefore seem permissible to review very briefly the present position of climatology in its relation to phthisis, in order, first, to formulate some definite suggestions for our choice of foreign resorts; and, secondly, to gather from a general consideration of the subject some practical hints to guide us in the selection of localities at home.

PRELIMINARY CONSIDERATIONS.

The first question which confronts us is the unfortunate one of sanatorium *versus* climate. There can be no doubt whatever that sanatoria such as Brehmer instituted afford the best treatment for phthisis which has hitherto been invented, and that in these institutions many patients now recover whose cases formerly would have been regarded as incurable. But to claim, as some have claimed, that it is a matter of indifference in what climate you place your sanatorium is to make an assertion which is wholly unwarrantable. The most successful sanatoria abroad, such as Görbersdorf and Nordrach, enjoy climatic advantages for which their sites were actually chosen. Moreover, there are many patients whom even sanatoria cannot cure. For the present, therefore, it would be an act of unreasonable folly to discard the assistance which a climate of proved value can afford to rational treatment.

Proceeding to the consideration of the exact amount of help which we may derive from climate there is a point, sometimes missed, which ought not to be lost sight of—viz., that our patients come to us, not to be merely "improved," but to be "cured"—cured, that is, in the sense of having their disease permanently arrested. Therefore, in judging of the merits of a climate we ought to ask ourselves, not how many cases it "improves," but how many it "arrests." We have some evidence that these two effects need not run parallel to each other. Sanatoria, according to statistics, improve more first-stage cases than high altitudes,[2] whilst high altitudes arrest more first-stage cases than sanatoria.[3] Again, sea voyages are remarkable for the great proportion of early cases which are generally improved by them—a number almost as great as at certain sanatoria and at Davos[4]; yet the percentage of arrests produced by sea voyages amongst such patients is much below the percentage at Davos or at the sanatoria.[5]

In speaking of arrest one would deprecate the distinction sometimes drawn between cases of arrest in which the relics of disease are clinically indistinguishable and cases of arrest in which disease has been more extensive and has therefore left traces which are clinically obvious. To call the former "cured" and the latter "arrested" can only create confusion. Patients in both cases are in a practical sense cured; in both they may live to the natural term of life or in both they may relapse.

To judge justly of a climate, one must, however, distinguish between its effects in early cases and its effects in cases more advanced It may be found that conditions which produce the best results in early phthisis may not be the best for later cases. Also one must remember in treating of climates that there are cases to arrest and cases which can only be retarded and alleviated—that there are climates to get well in and climates where getting worse entails less misery than elsewhere.

Lastly, the time has come when patients must be told that treatment in a home or in a foreign climate means treatment by a medical man, and when those who will not or cannot put themselves under medical care must be made to understand that they leave home at their own risk.

CLASSIFICATION OF CASES.

For practical purposes we may divide our patients thus: patients who should be kept at home; patients who should be sent away; and patients who must decide for themselves whether they remain at home or not. And in considering the last two classes we must further divide them into two very different categories—the wealthy and the poor.

Patients who should be kept at home.—No one would be likely to send away patients suffering from acute miliary tuberculosis, acute disseminated tuberculous pneumonia, or acute pneumonic phthisis in its acute initial stage. One would not advise patients who are the subjects of advanced phthisis with albuminuria, phthisis with ulcerative diarrhœa, advanced laryngeal phthisis, diabetic phthisis, rapidly advancing phthisis, or phthisis with persistent high temperature due to tuberculisation to leave the comforts and the care which home alone can provide for them. In the cases only of the poor, where home can provide neither care nor comfort, may a move be advised and then merely to the nearest institution which can supply the requisite nursing and luxuries. Setting these cases, therefore, aside from further consideration we turn to those for whom the question of change of climate can be reasonably entertained.

Patients who should be sent away.—If a patient is already living in a suitable climate his medical adviser would hesitate before advising him to change it, but for practical purposes such cases are but few.

Let us consider first foreign climates as we can order them for the wealthy. For practical purposes we may enumerate the following varieties of cases: (1) early cases, young, vigorous, uncomplicated, with little or no fever; (2) early cases with recurrent hæmorrhages; (3) early cases which have originated in pleurisy or pneumonia; (4) early cases with little or no fever but in weakly persons; (5) early cases, "irritative, such as follow influenza";

(6) "catarrhal phthisis"—i.e., with much bronchial catarrh; (7) "scrofulous phthisis"—i.e., with other tuberculous lesions, in bones, joints, glands, &c.; (8) fibroid phthisis; (9) bronchiectatic phthisis; (10) phthisis with emphysema; (11) laryngeal phthisis; (12) elderly patients; (13) erethric patients—i.e., "nervous, irritable subjects, neuralgic, dyspeptic, bad sleepers, with habitually quick pulse and dry harsh skins"[6]; (14) anæmic patients; and (15) patients with heart disease, arterial degeneration, or feeble circulation—"chilly" people. Taking these in order we shall probably not go far wrong in dealing with them as follows.

1. Early cases—the patients being young and vigorous and the condition uncomplicated, and there being little or no fever—should be sent to the Swiss Alps in preference to any other locality, and of the Alps we may safely take Davos as a type. Their chances of recovery in the Alps are greater than at any other place, at all events in Europe. There is rail all the way to Davos, and the journey from London takes about 30 hours. It is usually unnecessary to break the ascent. The end of September is the best time to arrive there, and the patient should be prepared to remain two winters and a summer. But a patient may go to Davos later in the season, although it is better not to arrive so late as the end of January.[7] On returning the descent should probably be broken, and Ragatz or Wesen might be chosen as a halting-place. Dr. Williams's[8] statistics for patients at high altitudes give the following figures:—Of 67 cases in the first stage with one lung affected 66 per cent. were arrested; of 52 in the same stage with both lungs affected 38 per cent. were arrested; and of 86 in the second and third stages 16 per cent. were arrested. No other climate in Europe can rival these results.

2. In early cases with recurrent hæmorrhages the Alps are also indicated, provided that a few weeks have elapsed since the last attack of hæmorrhage.

3 Early cases which have originated in pleurisy or pneumonia should also be sent to the Alps.

4. Early cases, uncomplicated, with little or no fever but in weakly persons, *if they do not feel cold easily* may also do well at Davos Usually, however, a warmer climate will have to be recommended. If sent to Davos they should break the ascent at some intermediate altitude, such as Ragatz or Wesen. If Davos is decided against they may be sent to Egypt, the Riviera, or to a sanatorium such as Nordrach. The season in Egypt is an exceptionally short one. Patients arrive in November and must generally leave in March. The journey takes about six days from London, and three of these are spent at sea. Helouan near Cairo, Luxor, or Assouan may be chosen for the season. The results seem to be excellent, but at present I cannot discover any precise statements of percentage of arrests. Patients leaving Egypt must find some other resting-place till the end of May at earliest. The Riviera is nearer home, less expensive, but apparently less certain in promoting arrest. It seems unfortunate that separate statistics are not available for the different towns along it. It is difficult to imagine that mistral-swept Hyères and mountain-sheltered Mentone produce the same improvement. Patients should arrive on the Riviera about the last week in October and should not return to England before the end of May If the weather becomes too hot they may move inland to Grasse or travel north in May to some pleasant place like Badenweiler in the Schwartzwald. Nice is to be avoided, Cannes is uncertain, Hyères is very windy in February and March. San Remo[9] and Mentone are probably amongst the best places on the coast. It is curious that whilst patients who have wintered in Davos can return to England in May with little danger of chills patients from the Riviera are very much more vulnerable.[10] The Riviera seems in this respect to occupy a position intermediate between the high Alps and sea voyages, for the tendency to relapse on landing from a sea voyage is a well-known characteristic. It cannot, however, be imagined, after a careful perusal of the literature, but that with the constant supervision to which phthisical patients are at last submitting, with the avoidance of chills and of those social excitements which so often prove disastrous, some parts at least of the Riviera should yield in selected cases most satisfactory results.

With regard to sanatoria the most famous ones only may be considered here. The doctrine of systematic supervision of a phthisical patient's whole life in an institution for the purpose where continual open air, abundant pure food, and regulated exercise are the essence of the treatment, was first formulated by Brehmer and was put in practice at Görbersdorf in Silesia, a small village in a sheltered valley 1700 feet above sea-level. There the results attained surpassed all previous European records, and daughter sanatoria began to be erected in other parts of Germany. Of these, perhaps the most notable are Dr. Dettweiler's at Falkenstein and Dr. Walther's at Nordrach. In England the Nordrach system is generally gaining in favour and the excellent institutions now rising in various parts of these islands are more or less modelled upon it. It is difficult at present to compare the results achieved at different sanatoria, but of their general value an idea may be gathered from the statistics which Manasse published some years ago from Görbersdorf.[11] Of 1390 cases in the first stage 27·8 per cent. were arrested; of 2225 in the second stage 6·83 per cent. were arrested; and of 1417 in the third stage 0·48 per cent. were arrested. There is no special season for going to these sanatoria. The time merely depends on the occurrence of vacancies. The length of stay depends upon the case and is fixed by the medical man in charge of the institution.

5. Post-influenzal cases with considerable irritation are said to do particularly well on the Riviera.[12]

6. "Catarrhal" phthisis is the one variety of the disease which is said to do well at Madeira. The voyage to Funchal from London occupies about three and a half days in the fine Cape steamers. It is the only place within so short a distance of our shores where winter is really absent. But for the early cases which do so well at Davos a winter in Madeira may be a terrible mistake. Patients liable to diarrhœa ought not to be sent to Madeira and all patients must be instructed to boil all the water they drink. When the best has been said of Madeira there still remains in the mind the feeling that it is a risky climate and personally I should prefer to send "catarrhal" cases to a sanatorium than to run the risk of recommending it.

7. Patients who are the subjects of "scrofulous" phthisis may be sent to the Riviera.

8. Sufferers from fibroid phthisis will probably do as well on the Riviera as anywhere.

9 In cases of bronchiectatic phthisis the patients will perhaps do best in Egypt.

10. In phthisis with emphysema the patients do well in Egypt or on the Riviera.

11. Patients suffering from laryngeal phthisis may perhaps do best at San Remo or Mentone. Dr. Walther, however, tells me that such cases recover at Nordrach, and so Nordrach will naturally be thought of in sending them abroad.

12. Elderly patients will find Egypt or the Riviera their best wintering place.

13. Erethric patients will find Egypt the best place.

14 and 15. Anæmic patients, patients with heart disease, arterial degeneration, &c., should probably choose Egypt or the Riviera.

It will be observed that a very limited number of localities have been mentioned. By thus confining consideration to the few needless complexity is avoided and the remarks are limited to places which have at least well-established reputations. There are, however, other foreign health resorts which have either unquestioned merit or are so well known that patients will inquire about them. The chief of these are as follows. The Andes in the neighbourhood of the Equator possess probably the best climate in the world for phthisis. It is asserted that at Jauja in Peru 79 per cent. of all cases are arrested.[13] But although the journey to Jauja is a shorter one than that to Australia—only about four or five weeks from London—it is scarcely of such a character that one could recommend it to many patients. Much of the distance lies within the tropics with their special dangers to phthisical patients. The yellow-fever country has to be crossed at Panama, and finally the journey from Oroya, where the railway from Lima ends, is two days on muleback over passes higher than the highest European mountain, so that mountain-sickness often overtakes both man and mule. The accommodation, too, on arrival, the food, language, and society, are Spanish, and the invalid should be prepared to rough it during his residence Once established there, however, he will find the climate one of everlasting spring and may remain at Jauja until he has fully recovered. The accounts which have reached us from time to time of this valley, as well as of Quito, Santa Fé de Bogota, of La Paz in Bolivia, and other places in those regions, are certainly extraordinary, and, if readier means of access should sometime become available, the profession will no doubt endeavour to utilise them for Europeans. Colorado is probably as valuable as Davos, and has the advantage of affording the essentials for permanent residence and occupation. But the journey is a long one and the living is expensive Southern California possesses a climate which has been greatly praised. But the distance is very great and exact statistics do not seem available The Adirondacks sanatoria produce equally good results with the European. The high inland plains of Australia and South Africa afford for vigorous young men with early phthisis an excellent chance of recovery and a field for enterprise. The Darling Downs of Queensland and the Karroo at the Cape have yielded some of the best results which climate can afford. But the patient who goes there should remain there till he is well. He must also be prepared to rough it The Canaries seem to have been inadequately tested To class the whole group together is a very great mistake A patient of mine whom I sent to Las Palmas 10 years ago is now quite well and lives all the year in England. Algiers has proved useful in a considerable number of cases Malaga in spite of its want of sanitation seems to have been singularly successful Of Dr. Williams's 10 patients every one did well [14]

Lastly, it is necessary to say something of sea voyages So much has been written about them that it is impossible to pass them over Perhaps there is no important subject in medical climatology on which such widely differing views have been expressed, and taking all the "pros" and "cons" into account we shall probably do wisely in ceasing to recommend them This is so strong a statement and one so much at variance with general opinion that it is necessary to explain the reasons which support it. To gauge the merits of sea voyages we must compare them with other modern means of climatic treatment Consequently Dr Walshe's [15] oft-quoted eulogium, which follows five pages after his reference to "the startling *quasi* sensational novelty of treatment in the Alps," must be regarded as out-of-date No one can read the admirable accounts of the voyage to Australia in a sailing ship round the Cape—admittedly the best voyage—given by Lindsay [16] and by Wilson [17] without feeling the gravest misgivings about the wisdom of sending patients through the probable vicissitudes The gales and sea sickness of the Channel, the depressing heat or steamy vapour of the Doldrums, and the heavy seas of the Roaring Forties are a large price to pay for the intervening stretches of pleasant breezy weather Dr. Williams's [18] statistics give 12 per cent as the proportion of arrests in first stage cases sent to sea This does not compare favourably with 27 28 per cent on dry land at Görbersdorf, or 57 per cent. at Davos Again, while Davos arrests 16 per cent of second- and third stage cases, and Gorbersdorf 6 83 per cent second-stage, and 0 48 per cent third stage cases, not one of Dr Williams's second or third stage cases was arrested. A careful perusal of works on the subject convinces me that Dr Coupland Taylor,[19] himself a patient as well as a medical man, sums up the matter wisely. He says. "Any slight advantage there may be as to the pureness of the air of the ocean is, I maintain, far outweighed by the manifest disadvantages to an invalid at sea, such as the close ill-ventilated cabins, the draughty saloons, the weakness and straining caused by sea sickness, the damp sea fogs, the enforced confinement below during bad weather, and the great trial to an invalid of passing through the tropics"

It is sometimes said that "quiescent cavity cases" do very well on a voyage They certainly do not *get* well, to judge by Dr Williams's figures But the opinion is so far dangerous that it is almost certain to lead to a number of advanced cases being sent away to sea For such cases—advanced cases—Dr Coupland Taylor [20] says, "The sea is simply a fatal remedy" Dr. Burney Yeo [21] has done good service in drawing attention to this point and it is so important that I quote at length the following. "Dr. L. E Shaw . . . says: 'No one who has acted as surgeon to an invalid ship, who has seen patients with advanced phthisis suddenly transferred from their comfortable invalid homes on land to the small accommodation and scanty luxuries which, with the best intentions, the authorities are able to provide for them at sea; no one who has watched the fearful anxiety of these patients to get back to their homes when they find their disease progressing, and who, finally, as their best and only friend, has received their last messages for their relatives, could possibly recommend a long sea voyage as a justifiable treatment in such cases" Again Dr Yeo [22] quotes Dr J de B. Griffith, physician to the Melbourne Hospital, who writes: "My personal experience of sea voyages and my position at the antipodes enable me to speak with some knowledge of the effects of a sailing-ship voyage on delicate people, and I feel quite sure that medical men do not know what they are advising when they recommend patients in advanced phthisis to come to Australia in a sailing ship" Dr. Taylor [23] mentions one voyage in which of 10 phthisical patients six died soon after their arrival

Of course, when a phthisical patient has made up his mind to settle in the great inland plains of America, Australia, or South Africa he must undertake a sea voyage Even then, it seems to me, this should be regarded as a risk. Dr. B J. Guillemard,[24] in writing of the voyage to the Cape, says: "It has been the custom to recommend a sea voyage to invalids as a universal panacea for every ill, but it must be strongly insisted upon that it has very real risks to the invalid, and for want of precautions many have arrived in Table Bay in a worse state of health than when they started."

No one of course will question the fact that phthisis in its early stage can sometimes be cured at sea, but, as sea voyages now are, early cases can be more certainly and safely cured on land The day may come when a sort of floating Nordrach will cruise continuously in the most health-giving and least tempestuous of oceans, but that day is not yet Meantime (unless special circumstances make a sea voyage desirable, such as an opening for employment on board ship in place of an unhealthy home), let the sea voyage be for the phthisical patient a means of transit and of transit only, and let the traveller choose as far as possible the fastest vessel and the safest route

Foreign climates for the poor are practically non existent

The question of home climates for the wealthy is the same as the question of home climates for the poor, and therefore we may proceed at once to the consideration of home climates generally. Some few years ago, I think I am correct in saying, it was usual in the profession to undervalue the climates of our own country. Now there is a tendency to think that, with the addition of sanatorium treatment, they are all that can be desired This latter view may prove to be correct, but when we come to the practical question of the best site for a sanatorium in this or that neighbourhood we soon begin to realise how much we have still to learn We can divide English climates into sedative and stimulant, inland and marine, autumn and winter, and such divisions are useful; but when we are asked to point to a definite place on the map and to say with confidence to a phthisical patient, "That is *the* place for you to go to, and your chances of recovery there amount to so much," I fancy most of us rather feel ourselves at a loss Yet that is what we ought to be able to do Although a great deal of valuable work has been done, as everyone knows, on the climate of England, we still know so little that we may approach it as almost a new subject If we want some sort of certainty in the placing of sanatoria we must investigate localities more closely than hitherto In such an investigation three methods of inquiry will occur to us especially 1 The collection of statistics of the results of treatment of phthisis in the area which we are studying, distinguishing between first-stage cases and cases more advanced and between cases arrested and cases only improved We may call this the *method of comparing curative effects* 2 The accumulation of meteorological records, temperatures, rainfall, sunshine, &c, together with comparison of soils, physical features, and so forth This may be called the *method of comparing physical peculiarities* 3 The observation of the death-rates from phthisis in the resident population with a view to finding the areas of lowest phthisis mortality. We may call this the *method of comparing phthisis immunities.*

[23] Op. cit., p 17

[24] Health Abroad, p. 63.

Of these it is obvious that the first is by far the most important since it alone can give really certain information. But it is not available. Dr. Theodore Williams's[25] interesting tables deal only with "improvements," and are therefore only suggestive. The sanatoria being established in different parts of the country will in years to come afford the necessary data and will then enable us to place home climatology on the same scientific basis as that on which a part of foreign climatology already rests. But for the present we must fall back on other methods of inquiry.

The second method by itself has led us into error on more than one occasion. Pau and Madeira are, so to speak, "some of our failures." Whilst many valuable facts are at our disposal, so many facts are uncertain, that to depend for choice of climate on a comparison of the physical peculiarities of a district is, it seems to me, almost to court mistake.

The third method, though far inferior to the first, is nevertheless worthy of more consideration than it has hitherto received. It is easy enough to ascertain the phthisis death-rates in the parishes and there is every probability that these will be practically accurate. There is not a very serious danger that phthisis nowadays will be mistaken at its termination. But the Registrar-General's reports deal with too large areas for the purpose. It does not, of course, follow that because a district is very free from phthisis that this freedom may not be due to merely accidental causes—i.e., causes other than climatological influence. If, however, it can be shown that over a considerable area the variations in the death-rate from phthisis follow closely the variations of some climatic influence, the conclusion may be fair that the freedom of certain places is climatic and not accidental. We may further test the soundness of this conclusion by examining other areas to see if the same law holds, and, still further, by endeavouring to test its truth by a reference to well-known climates abroad. Finally, we may endeavour to gain some explanation of the way in which the particular climatic influence produces the variations in the phthisis death-rate. We may thus arrive at a judgment that certain low-mortality areas for phthisis owe their comparative immunity to definite climatic advantages, and it is at all events worth trying whether or not such areas will specially promote recovery from the disease. It is not logically necessary that they should do so, but it certainly seems likely. We may remember that the places abroad which have yielded the best results in the treatment of phthisis are places where phthisis was known to be uncommon. At Quito and Jauja phthisis was said to be exotic, at Davos it was scarcely known, at Görbersdorf it was rare, and at Mentone it was eight times rarer than in London. I would suggest the establishment of sanatoria for phthisis in places ascertained to be climatically immune.

To illustrate this method of ascertaining the death-rates and taking their dependence upon climate I would refer to an inquiry which I have made in our own county with reference to one climatic factor. Amidst the vicissitudes of medical fashion I believe in the value of Devonshire. The Devon cattle at all events are remarkable for their freedom from tuberculosis. We have watched even hospital out-patients recovering in reasonable proportion. There are many areas in Devon where the death-rate from phthisis is far below the average. There are parishes in Barnstaple district, in Okehampton district, and in the neighbourhood of Exeter where for 10 years there has not been a death from the disease. The whole rural district of Axminster has a death-rate from phthisis of only 0·6 per 1000, Seaton has for 10 years had this same mortality among its residents. Sidmouth has a very low mortality from phthisis. It is needless to multiply instances. For purposes of illustration we may restrict ourselves to Devon, and in the matter of sanatoria for our poorer patients we must. In the rural district of Okehampton, in the centre of the county, there is a remarkable correspondence between wind-exposure and phthisis, and shelter from wet winds seems to determine a very low death-rate from the disease. For the figures I am indebted to my friend Dr. E. H. Young, and in another paper I hope to do fuller justice to his most valuable assistance. At the south-east angle of this district there is a group of three parishes,—Gidleigh, Chagford, and Drewsteignton—where the collective mortality from phthisis in the last 10 years has been 0·7 per 1000 per annum. As the average annual mortality for England is just about twice as great one may fairly call this group of parishes a low-mortality area. Should we regard this low mortality as climatic or accidental? The parishes in question are sheltered by the heights of Dartmoor from the prevalent wet winds. The west wind and the south-west wind have practically no access to them, and if we construct a map of the exposures of the Okehampton district parishes to these two winds and compare it with a map of the phthisis death-rates of the parishes we discover a correspondence which is singularly striking. If we go further and compare it with a map of the phthisis death-rates in the parishes among the females only the correspondence becomes more striking still. If, on the other hand, we compare geology, or rainfall, or exposure to other winds with the distribution of the death-rate from phthisis we find no such correspondence except that the north-west wind seems to have a slight amount of influence. From a study of the district, therefore, one is led to the belief that the low mortality of the three parishes is due at least largely to climatic peculiarities. Can we confirm this by examining the death-rates of other districts? In the rural districts of Barnstaple, of Newton Abbot, and of St. Thomas (the only districts which I have yet examined) we find the same relationship between the wet winds and phthisis. The most sheltered rural district in Devon as regards west and south-west winds is the Axminster district and it has the lowest death-rate from phthisis. Conversely the most exposed rural district in Devon has the highest death-rate from phthisis. A medical man who practises on both sides of a ridge of hills running north and south tells me that his phthisical patients die fastest on its western slope. In our own hospital at Exeter cases of phthisis do badly when the winds are blowing from the wet quarter. The belief is thus confirmed that the low mortality in question is due to shelter from these winds. Can we get any further confirmation from our knowledge of foreign places? To form on opinion on this point we may take such health resorts as have achieved undoubted success. Confining ourselves to those on which we have clear statements, Davos in the Alps, Colorado Springs in the United States, Nordrach in the Black Forest, and Görbersdorf in Silesia may be safely called successes. Davos, according to general agreement, is almost windless in winter except when the rare Fohn is blowing. Nordrach is well sheltered, and Görbersdorf gets no strong winds. Only Colorado Springs is windy, but all winds at Colorado Springs are particularly dry. Therefore in all these places strong wet winds are absent.

Finally, can we get any rational explanation which may tend to satisfy those who doubt the possibility of such an influence of special winds? Professor Beneke's experiments on the cooling of flasks of water exposed respectively to sea-breezes and to inland breezes demonstrated a more rapid cooling of the flasks which were exposed to the sea-breezes, which are, of course, the damper. Perhaps here lies the explanation. May we not suppose that exposure to prevalent wet winds is synonymous with the well-worn expression "exposure to cold and wet"? Altogether it seems reasonably clear that shelter from west and south-west has a great deal to do with the low phthisis mortality of the three parishes alluded to. So far, then, these parishes enjoy a climatic immunity, and therefore I would suggest that their area is one which might reasonably be tried as "curative." I have only made experiment of their curative power in a single case of phthisis, but that case, an early one, did exceptionally well. After spending the coldest months of one winter in the neighbourhood of Chagford the physical signs at the affected apex had practically disappeared. I should add, however, that this patient afterwards went elsewhere and relapsed.

I do not think that many people will assert that it is a matter of indifference where one places a sanatorium, but I fancy that many people imagine that the difference is small between one part of a county and another. That is a question which experience must decide. But it surely would be wiser before spending money on a building to endeavour to determine the district which is most promising. I would suggest the selection of low-mortality areas where there is reasonable evidence that the relative immunity is due to the local climate and within those areas to choose sites which shall satisfy those conditions which experience has shown to be important for success. The conditions may, perhaps, be stated thus: a dry soil, pure air, abundant sunshine, the absence of wind (may I say especially wet wind?), the absence of dust, the absence of fog, and the avoidance of the *immediate* sea front. By this last I would not by any means imply an avoidance of the coast. But the *immediate* sea-front seems certainly less desirable than a short distance from the shore. A high altitude I do not mention as it is not obtainable.

---

[25] Influence of Climate on Pulmonary Consumption, p. 56.

Patients who must decide for themselves whether they remain at home or not.—These patients may perhaps be enumerated thus (1) patients with early phthisis and some albuminuria; (2) patients with advanced phthisis; and (3) patients with recurrent hæmorrhage from a cavity. The practical difficulty arises in these cases chiefly with regard to foreign travel. We may therefore content ourselves with a brief allusion to places abroad.

1. Those with early phthisis and some albuminuria had better choose Egypt or the Riviera

2 Those with advanced phthisis had better let the Riviera be their limit of distance.

3. Those with recurrent hæmorrhage will be safest in a sanatorium.

There is also a class of patients who come into this category—viz, those whose wish it is to spend their last months amidst beautiful or interesting scenery. For these, of course, there need be no hard-and-fast rules. We must only ascertain that they have made up their minds and fully understand the exact reason for their journey.

CONCLUSION.

In concluding, I would like just to retouch the main outlines of this necessarily crude sketch. In the choice of foreign climates—the climates for the few—we have now some very definite indications, indications much clearer than some people seem to think. In the choice of home climates—the climates for the many—we have no such definite indications, and, indeed, we know much less about them than some of us are willing to admit. Sanatoria, whilst of immense value, do not supersede climates, and the success of our English sanatoria will depend largely on the sites which are chosen for them. Consequently, it seems to me that a study of home climates such as should give us the same precision in their selection as we now enjoy in the case of certain foreign climates is a matter of immediate importance. If we are to reap in England the greatest benefit for the greatest number of phthisical patients for whom we are responsible we ought to combine the erection of sanatoria with the selection for them of those localities which seem most promising from a climatic point of view.

I have to express my acknowledgments to the authors of whose writings I have freely availed myself, as well as to those friends at home and abroad who have been so good as to give me much valuable information.

Exeter.

FOUR CASES OF PERFORATION (GASTRIC AND DUODENAL) SUCCESSFULLY TREATED BY OPERATION.[1]

BY A. CHRISTY WILSON, M.D. EDIN.,

SENIOR SURGEON TO THE DONCASTER INFIRMARY.

MANY cases of perforating ulcer have been recorded and each of the following cases presents features of interest

CASE 1.—A man, aged 28 years, was admitted into the infirmary at 7 P.M. on May 19th, 1898, in a collapsed condition, complaining of intense pain in the epigastrium. For six years he had been treated for gastric ulcer, and hæmatemesis had occurred several times. During the day he had eaten heartily of cold fried fish, hot preserved peas, and new bread, washed down with copious draughts of beer. His abdomen was as hard as a board, without movement on respiration and with absence of liver dulness. Ether was administered four hours after perforation and a median incision was made from the ensiform cartilage to the umbilicus and a perforation was soon found on the anterior wall of the stomach half an inch from the pylorus. The perforation was surrounded by some induration and was difficult to get at owing to an overhanging enlarged liver. The ulcer was stitched up, then came a row of Lembert silk sutures, and over all I stitched a fold of omentum. In order that the pelvis should be thoroughly cleansed a second opening was made above the pubes and a quantity of foul fluid and some peas were cleared out. Several gallons of sterilised normal saline solution were used for flushing, and the wounds were closed with silkworm gut sutures which inclosed the whole thickness of the abdominal wall. He had a little bronchitis, probably from the ether, but recovered rapidly, and was discharged from the infirmary under five weeks from admission. 18 months later he came to show himself greatly delighted that his dyspepsia was cured and that he could eat all kinds of food with impunity.

CASE 2—A man, aged 21 years, was awakened at 3 A.M by a sharp pain in the stomach and took a teaspoonful of laudanum with such marked relief that at 6 o'clock he walked two miles to his work. He had very little pain until next day, when I was called in. I found that there was a history of dyspepsia and the presence of severe pain shooting from the edge of his left ribs to the left shoulder blade, every breath causing a gasping moan. There was no sickness or friction and it was impossible to say whether it was gastric perforation or diaphragmatic pleurisy. I advised operation, but could not gain consent until 92 hours after the onset of the acute symptoms. A median incision was made, and as soon as the peritoneum was opened there was an escape of fœtid gas and pus from a cavity separated by dense adhesions from the general peritoneal cavity. The small oval perforation was difficult to stitch up, as it was well under the left ribs, and the stomach was so tightly bound with adhesions that it could not be pulled forward. The left lobe of the liver and the stomach were thickly covered with putrid lymph, a large quantity of which was removed. The patient was discharged cured in two months and continues to enjoy excellent health.

CASE 3—In this case, that of a man, aged 22 years, perforation took place soon after a hearty meal of beef, potatoes, peas, bread, butter, and beer. My son, Dr. W. R. Wilson, sent him to the infirmary and five hours after perforation I found the opening in the centre of an induration two inches in diameter and half an inch thick, to the left of the middle line. A large amount of food had escaped and there were flakes of lymph in all directions. After stitching the ulcer up with two rows of sutures a second incision was made in the hypogastrium and flushing and sponging were vigorously applied. The patient was discharged in less than a month and has gained 21 pounds and is in robust health.

CASE 4—The patient in this case, one of perforating ulcer of the duodenum, was a man, aged 48 years, who for several years had been troubled with indigestion, but whilst employed as usual at his hard work one morning was seized at 11 30, three hours after breakfast, with severe pain in his epigastrium. He presented all the symptoms of perforation, but he refused operation until 28 hours after its occurrence. Ether was administered, and as soon as the peritoneum was opened by a median incision a quantity of bile-stained mucus escaped, suggesting perforation of the gall-bladder. The perforation was found in the anterior wall of the duodenum, about an inch from the pylorus The perforation was closed with a double row of stitches, the wound being enlarged to within four inches of the pubes. There were all the signs of advanced peritonitis, all the viscera having large patches of yellow lymph adhering to them, and the pelvis was full of septic fluid The "toilet of the peritoneum" was performed most carefully with the aid of large pieces of lint wrung out of biniodide of mercury solution. Coil after coil of the intestine was pulled out, scrubbed, and put in again, and the liver, stomach, and pelvis were cleansed as thoroughly as possible Normal saline solution was freely used for flushing, as in all the other cases. His recovery was slow, but he continues in his regular hard work and in excellent health.

The above are brief notes of all the cases of gastric ulcer that I have had, and not selected cases. Perforating ulcer of the duodenum is much commoner in men than in women, but that of the stomach is the reverse. My old college friend, Dr. G. H. Hume of Newcastle, has recently published all his cases of operation for perforating gastric ulcer—11 with six recoveries and every one was a woman. The percentage of recovery is usually stated to be in proportion to the length of time from perforation to the operation, but in my second case 92 hours elapsed Perforating ulcer of the duodenum is said to be much more fatal than gastric and yet my man recovered in spite of 28 hours' interval. I am of opinion that sex influences the result more than duration. Most women who have perforation are profoundly anæmic and fortunately my men were not. Thoroughness of cleaning is, I believe, of very great importance. In all four cases the pelvis contained a large amount of purulent looking fluid, large flakes of lymph, and in two cases a good deal of food. A second incision above the pubes affords better access to the pelvis and leaves a stronger abdominal wall than a long single incision.

---

[1] A paper read before the Leeds and West Riding Medico-Chirurgical Society on May 3rd, 1901.

My best thanks are due to my colleague, Dr. E. W. Selby, for his able assistance during the operations, and to Mr. W. R. Willey, house surgeon to the Doncaster Infirmary, for his unremitting care of the patients and for notes of the cases.

Doncaster.

THE
TREATMENT OF PUERPERAL ECLAMPSIA BY SALINE DIURETIC INFUSIONS.

BY ROBERT JARDINE, M.D. EDIN., M.R.C.S. ENG.,
F.F.P. & S. GLASG., F.R.S.E.,
SENIOR PHYSICIAN TO THE GLASGOW MATERNITY HOSPITAL; EXAMINER IN MIDWIFERY TO THE UNIVERSITY OF GLASGOW; PRESIDENT OF THE GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

THE subject of puerperal eclampsia is one to which a great deal of attention has been paid for a very long time, but we must admit that our knowledge, especially of the pathology of the condition, has not advanced much beyond that possessed by our predecessors. However, I think we may fairly claim to have made some improvements in the methods of treatment, but much remains to be done before we can approach these cases with confidence. It is now generally admitted that the fits are caused by the action of a toxin which has accumulated in the system of the mother. Some observers have maintained that micro-organisms are the prime factors, but of this no sufficient proof has been advanced. The toxin seems to me to be a waste product from tissue metabolism, but its exact source of origin I shall not attempt to theorise about. It has been maintained that on the death of the fœtus the albumin quickly disappears from the urine. If the toxin causes the albuminuria, as I believe it does, this would point to its origin from the tissue metabolism connected with the development of the fœtus. This statement of the disappearance of the albumin from the urine on the death of the fœtus is one which I dispute, as I have now seen three cases of eclampsia and one of severe albuminuria with macerated fœtuses and in all the albumin was abundant.

If there is a poison in the maternal blood it should affect the fœtus. That it does so has frequently been shown. The fœtus has actually been observed to be convulsed *in utero*, and I have seen several cases of convulsions during the first few days of the infant's life. I have also seen two children born in a perfectly rigid condition as if they had died in a convulsion. Sir James Simpson was the first, I believe, to point out the presence of albumin in the urine of the infant. In every case that I have examined it has been found. I have also found albumin in the urine of several children whose mothers had severe albuminuria but were rescued from eclampsia by prompt treatment. The poison seems to act on the fœtus in much the same way as it does on the mother.

The condition of pregnancy adds a new factor to a woman's economy. Her excretory organs are called upon to deal, not only with the ordinary waste products of her own system but also with those generated in the rapidly-growing uterus and its contents. The rapid development going on must of necessity give rise to a very large amount of waste products which has to be got rid of through the maternal system. A very important question arises—viz., what are the channels through which these waste products are removed?

First we may consider the alimentary channel. Constipation is the rule in pregnancy and markedly so with eclamptic patients. The importance of free purgation has always been recognised in treating the condition. I think one may fairly claim that the elimination of waste products through this channel is somewhat in abeyance. When the presence of albumin in the urine was detected attention was naturally called to the kidneys. The kidneys are undoubtedly out of order, but except in cases of pre-existing nephritis one cannot say that they are seriously diseased. They recover so quickly that one can only say that the derangement is temporary. The condition, I believe, is caused by the toxin acting very much in the same way as a poison like turpentine or cantharidine does. Albumin, and often blood, appears, excretion is lessened, and in some cases there is total suppression of urine.

Within recent years attention has been called to the condition of the liver. There is no doubt that this organ shows considerable degeneration. In many cases the condition is quite apparent to the naked eye. Hæmorrhages under the capsule or into the liver substance are sometimes seen. In a recent case there were numerous hæmorrhages all over the liver under the capsule and the liver substance looked like a compressed rotten sponge. Dr. Carstairs Douglas, the pathologist to the Glasgow Maternity Hospital has furnished me with the following report on the liver condition in four cases.

No. 1.—Liver cells dull, cloudy, and irregular. Indications of necrosis and fatty changes, the cells appearing to contain some amorphous material.

No. 2.—Cells in some parts show much disintegration and contents consist of fine molecular débris. In other parts they are large, cloudy, indistinct, and in many cases the nuclei are very large

No. 3 —Cells are cloudy and dull; in many cases are much separated from one another and many stain badly. Some amorphous structureless material is sometimes found lying between them

No 4.—Cells stain badly, small hæmorrhages are found here and there; there is distinct chronic venous congestion and deposit of pigment. Macroscopic appearance of this liver was very striking.

In three out of four of these cases the liver on section presented a very peculiar brown tint, and brittle, almost honey-combed, consistency. It looked more like ginger-bread than anything else.

Last year one of my patients, after having had 28 fits, was apparently doing well. The albumin had almost entirely disappeared, the kidneys were excreting very freely, and the coma had passed off. On the fifth day the patient relapsed into deep coma and to all appearance was dying. After a third large infusion and a hot pack she began to improve and in two days she again became quite sensible and she recovered. During this second attack of coma the urine was very deeply loaded with bile pigment. If the kidneys had not been acting very freely I feel sure that she would have died. Her liver was evidently considerably deranged. I am firmly convinced that the liver plays an important part in the ridding of the system of the poison, but how it acts I do not know.

In a paper read before the Obstetrical Society of London on April 3rd Dr. Hey Groves maintained that in eclampsia there was an increased coagulability of the blood which gave rise to multiple minute thrombi and thus caused the fits. In pregnancy there is an increase in the coagulability of the blood, but I am not aware of any observations which would confirm Dr. Groves's theory. At present my friend Dr. Carstairs Douglas is carrying out experiments on this very point, but we cannot as yet make any definite statements. We have frequently found ante-mortem clots in the heart, but not specially in eclamptic cases. The minute hæmorrhages referred to by many observers I have always considered an effect and not a cause of the convulsions. During pregnancy a woman's nervous system is in a very unstable condition. It is well known that a sudden shock will often precipitate convulsions. Any prolonged mental strain will predispose to an attack. Last year we had two cases in the wives of soldiers on active service. It seems to me that the convulsions are caused by the direct action of the toxin on the nervous centres which are already in a very unstable condition.

TREATMENT.

If it is admitted that we have a toxic substance in the system the aim of our treatment should surely be either to administer an antidote or else to clear the substance from the system as quickly and as effectually as possible. As we do not know what the substance is we are unable to furnish an antidote. The method of treatment which I have adopted is one which aims at clearing the system of deleterious substances through the natural channels—i.e., through the bowels, the skin, and the kidneys. This seems to me to be more rational than giving drugs to check the fits. If we can remove the cause the fits will soon cease.

If we were able to keep all pregnant women under observation and to treat all cases of albuminuria by milk diet, saline purges, and diuretics, eclampsia would be practically unknown. We have all seen cases rescued from convulsions by prompt treatment. At the end of last year I had two cases under treatment for a month; one in private practice and the other in hospital. In both there was marked œdema and severe headache and [illegible] daily purging with salts [illegible] and diuretics both patients went to full time and were delivered of live children. In one case the child showed albumin in the urine and in the other I did not have an opportunity of examining the urine, but the child suffered from marked œdema of the arms and legs for about 10 days. In that case the salts had evidently purged the fœtus in utero as the liquor amnii was like thin tar.

When the fits have commenced we have no time to spare. Absorption through the alimentary canal is largely in abeyance. To move the bowels very large doses of medicine are necessary. A hypodermic purgative would be most useful, but unfortunately we do not possess one. Croton oil which is so useful in other cases often fails here. I have given five minims without any effect and have twice seen œdema glottidis caused by it. From one to three ounces of Epsom salts given through a stomach-tube unless the patient is quite conscious is the purgative which we now use.

To get a good action of the skin a hot pack or steam bath is most useful. Pilocarpine is too depressing and if there is œdema of the lungs, as there usually is, it may kill the patient.

To act on the kidneys diuretics by the mouth cannot be depended upon. As a rule the patient cannot swallow and her absorptive powers are very low. Dr. Groves and other writers state that there is no diuretic action after the use of normal saline solution. That may be so, but I maintain that there is a diuretic effect obtained when in addition to the normal saline solution acetate of soda or bicarbonate of potash is used. It is perfectly true that it is the second or third day before we have a very large amount of urine excreted. In most of the cases which I have dealt with there has been almost total suppression of urine. After the infusion we, as a rule, have got from two to four or more ounces of urine per hour within the first few hours. Besides flushing the system it dilutes the poison and stimulates the patient. It acts in the same beneficial way as the normal saline solution does in septic cases. I am firmly convinced that it has an effect in controlling the fits. The cases which I have treated without any drugs to control the fits have done quite as well as have those in which the drugs were given. A short time ago I reported a case in the *British Medical Journal* in which the patient had had 22 fits. They were recurring so quickly that she had three during the time the nurses were washing her. After the infusion and hot pack she never had another. As she had been delivered 12 hours it was not a case in which the emptying of the uterus had relieved her.

The infusions are given under the breast or into the abdominal wall. A medium-sized Potain's trocar and cannula with three or four feet of tubing and a funnel is the apparatus which I use. Messrs. Gardner of Edinburgh have fitted up a very convenient one for me. The apparatus should be sterilised and the skin thoroughly cleansed. From one to three pints can be run in under the breast in a few minutes. The puncture should be covered with strapping. Messrs. Burroughs, Wellcome and Co. have made up soloids of acetate and chloride of soda, one drachm in each. One of each should be added to each pint of sterilised water at a temperature of 104° F. as it cools somewhat in the tube With ordinary precautions there is no fear of sepsis. I have given over 200 infusions and have never seen any bad effects. There is considerable tension in the part, but absorption is so quick that this is soon relieved. If necessary the infusion may be repeated several times. As soon as the patient can swallow milk should be freely administered.

As regards controlling the fits I have used all the drugs in general use, both alone and in conjunction with the infusions. Morphia, which has given such good results in the hands of some, has not given me good results. I am perfectly sure that it lessens excretion from the kidneys. My experience is leading me to give up using anti-spasmodics.

For some time I have been considering the advisability of administering oxygen[1] in bad cases and I intend giving it a trial. One would imagine that it ought to do good, and at least it can do no harm.

The obstetrical treatment has varied very much in different hands. The most difficult cases to deal with are those in which labour has not come on. The uterus should be left alone unless the fits continue in rapid succession. If the cervix is at all rigid incision is preferable to forced dilatation. Cæsarean section has been advocated for such cases but the results have been exceedingly bad. By incising the cervix one can deliver as quickly as by Cæsarean section and the shock is very much less. Any bleeding from the cervix would be beneficial to the patient and if it is excessive it can easily be controlled by stitches. If the case is well on in labour delivery should be effected at once. In all operative interference the patient should be kept deeply under chloroform to prevent shock.

Dr. Munro Kerr, who is now my colleague in the Glasgow Maternity Hospital, has collected all the cases of eclampsia treated in the hospital during the last 15 years. Under the old methods of treatment the death-rate was 47 per cent. This is very high, but it must be borne in mind that the majority of the patients are sent in after they have been having convulsions for many hours. It is rare for us to get them within 12 hours of the first fit. Since the infusions were used the death-rate has fallen to 24 per cent.

In a paper which is to appear in the *International Clinics* I have analysed the cases treated by myself up to the end of last year—21 in the hospital and one in private practice. "An analysis of these 22 cases shows that 17 were primiparous and five multiparous. One half of the labours were at full time and in only one case did the fits begin during the puerperium. Thirteen of the children were born dead and 10 alive, there being a case of twins among the latter. Of the dead children two were macerated, three were delivered by craniotomy, and three were too premature to live, so that of the 23 children only five were lost which might possibly have been saved. Of those born alive one was premature and only lived two hours. Of the 22 mothers three died, but one of the deaths was due to a perforating duodenal ulcer after recovery from the eclampsia. Even counting that as a fatal case, three deaths in 22, or 13 64 per cent., is certainly a very low death-rate." The first patient who died showed double pneumonia, multiple ulcers in the stomach, and patches of congestion throughout the intestines. She was treated with morphia and during the 44 hours that she was in the hospital we could get neither the bowels nor the kidneys to act. She only excreted 11½ ounces of urine during the whole time. The second fatal case was the one with the duodenal ulcer. The fœtus was macerated The third patient was delivered by craniotomy. The true conjugate measured three and a half inches As the child was dead craniotomy was done at once. The liver was markedly degenerated. The treatment has lowered the hospital death rate from eclampsia by about 50 per cent. and we have also saved more children than by the older methods. Dr Groves remarked in his paper that all who had tried the method were enthusiastic in its praise. I can endorse this statement as I have frequently heard from men on the subject. Most of the objections raised have been on theoretical grounds, but a little practical experience—and I have had not a little—is worth a vast amount of theory.

Glasgow.

Presentations to Medical Practitioners.—Mr. William Whitworth, M.R.C.S. Eng., L.S.A., was on June 6th presented by the members of the St. Agnes (Cornwall) branch of the St. John Ambulance Association with a silver inkstand suitably inscribed as a mark of appreciation for his services as honorary lecturer.—Mr. Stewart Lockie, M.D. Edin., of Carlisle, has been presented with a testimonial, consisting of a cheque for £300, a silver flower bowl, and an album register of the subscribers, who place on record their appreciation, especially of his eminent services in connexion with the medical charities of the city and district.—On May 31st, at the Town Hall, Huddersfield, Mr. E. G. Annis, medical officer of health of Huddersfield, who is leaving the town to enter on a similar appointment in the metropolitan borough of Greenwich, was presented by the Mayor with a drawing-room lamp bearing the inscription, "To Dr. Annis, from his brother officers, Huddersfield, 1901." It had been subscribed for by the principal officers of the corporation.

ROYAL DEVON AND EXETER HOSPITAL.

A CASE OF OVARIAN TUMOUR COMPLICATED BY TUBERCULOUS PERITONITIS; OPERATION; DEATH FROM TOXÆMIA.

(Under the care of Dr. HENRY DAVY and Mr. ARTHUR C. ROPER.)

THE association of tuberculous peritonitis with an ovarian tumour is certainly rare, and the presence of the peritonitis would be likely greatly to obscure the diagnosis. The most remarkable point about the case recorded below was the sudden death which occurred only a little more than 24 hours after the operation. In the absence of a complete necropsy it is impossible to say what was the cause of death, but the explanation suggested that it was the result of a toxæmia is certainly possible. For the notes of the case we are indebted to Mr. Manning, assistant house surgeon.

A woman, aged 39 years, was admitted into the Royal Devon and Exeter Hospital on March 1st, under the care of Dr. Davy, for extreme distension of the abdomen which had gradually reached its present condition during the previous six months. The patient stated that she had suffered from vomiting and pain in the epigastrium ever since she was 15 years of age. She was fairly well up to six months before admission when she was confined of her seventh child. The confinement was normal and satisfactory and the child was well. Five or six weeks after the confinement, when she was about again, she noticed what she called "indigestion." This troubled her with vomiting about half an hour after taking food. She had gnawing pain in the epigastrium and between her shoulders which the vomiting relieved. She suckled her child for nine weeks when the milk "went away." She noticed that her abdomen was becoming larger, but beyond the gnawing pain and vomiting, which continued up to admission, she saw nothing else amiss with herself. She did not notice that she lost flesh till a month ago, since when she had wasted rapidly. She had always been thin. She had had no previous illness. Her parents were alive and in good health. Four of her sisters were living; one died a year ago from tuberculosis at the age of 42 years. Her two brothers were both alive and well.

On admission the abdomen was enormously distended and fluid thrill was readily obtained. The chest was extremely emaciated and there were signs of phthisis in both lungs. The heart was normal with the exception of an accentuated pulmonary second sound. The urine was normal. The arteries were thickened. Paracentesis was at once performed and seven pints and two ounces of blood-stained fluid were withdrawn. After the operation it was possible to feel a nodular, freely moveable mass in the abdomen, just below and to the right side of the umbilicus. This mass seemed to be of about the size of an orange and loosely connected with other smaller lumps. On March 2nd the patient had been more comfortable since the paracentesis. The pulse was regular in force and frequency and of high tension. On examination of the abdomen large veins were seen coursing over it. The direction of the stream was upwards. There was still a fluid thrill and there was dulness in the flanks. The nodule to the right of the umbilicus was very tender and was not fixed below, but seemed to have some connexion with the pelvic viscera by a slender stalk or adhesion.

Mr. Roper was asked to see the case and advised laparotomy. On March 13th the abdomen was opened by the usual incision and a quantity of blood-stained ascitic fluid escaped. A large tumour then became apparent filling the abdomen and pelvis. Some organised and vascular parietal adhesions being dealt with it was found that the tumour was chiefly attached to the omentum which seemed to be incorporated with it. The omentum was red and fleshy with no trace of fat or of its ordinary appearance. The omentum was ligatured in three or four loops and the tumour was cut away from it. The only other adhesion was to the abdominal wall on the right side just above Poupart's ligament, and this peeled off easily. The tumour, which was apparently a multilocular ovarian cyst, but with fluid too viscid to flow through any trocar, was of about the size of a Rugby football, and was delivered through an enlarged incision. The ovaries were looked for, but only the left one was found. The whole peritoneum, both visceral and parietal, was studded with miliary tubercles. The abdomen was freely flushed with boiled water, a considerable quantity of which was left in, and the wound was closed with a rubber drain at the lower end. The patient bore the operation well.

On the morning of March 14th the patient had been sick only once since the operation. Her pulse was good and her general condition was most satisfactory. Owing to the escape of a considerable quantity of the fluid left in the abdomen at the operation, the dressings had become wet and were changed. The wound was quite satisfactory. The drainage-tube was removed. At 2 P.M. the patient was suddenly taken worse after an action of the bowels; she complained of severe abdominal pain and of a feeling of faintness. The pulse was small and 160. A considerable quantity of the blood-stained fluid again escaped from the wound and saturated the bedclothes. The temperature was 100° F. She was transfused with saline solution, and strychnine and digitalin were injected hypodermically, but she rapidly sank and died at 5.30 P.M.

A post-mortem examination was not permitted but the abdomen was examined through the wound. There was a considerable amount of blood-stained fluid, much of which was doubtless water left after the operation. The ligatures were all secure though the distal portions of the ligatured omentum were covered with thin blood-clot. This was sufficiently accounted for by oozing from the fleshy substance of the omentum distal to the ligature. The universal miliary tubercles were corroborated and there were no adhesions of the intestine of importance. What was taken to be the right ovary (which it will be remembered could not be discovered at the operation) was found deeply imbedded and adherent to the bottom of the right pelvic fossa. It was so adherent that it was torn in getting it to the surface, but there was no doubt in the minds of any of the four surgeons present at the examination that it was the ovary. Unfortunately, feeling no doubt about the matter, it was not preserved. The adhesion to the abdominal wall over Poupart's ligament was readily discovered.

Remarks by Mr. ROPER.—This case presents many points of interest. In the first place, the large tumour was not suspected until after the paracentesis which was urgently needed and performed immediately after the patient's admission to the hospital. Then the diagnosis when I saw her a few days later was quite doubtful, lying between malignant disease of the omentum with ascites from irritation or obstruction and tuberculous peritonitis with an ovarian cyst. Had it not been for the signs of phthisis in the chest I should have favoured the former diagnosis inasmuch as the tumour was evidently attached above, and, with the exception of the cord-like process referred to in Mr. Manning's careful notes, was apparently (and, as subsequently appeared, really) free below. Vaginal examination yielded little information, as the fluid obscured the tumour to the touch. The nodular feel of the tumour was more suggestive of malignant disease than of ovarian. The suggestion which the notes convey of separate masses is accurate as a description of the sense conveyed by touch, but must not be read as an opinion, as a large tumour was diagnosed before operation, though the actual size was greater than we expected to find. Secondly, the association of ovarian disease and tuberculous peritonitis is, I believe, rare. Thirdly, the tumour was to all appearances ovarian, a multilocular cyst, but it had no ovarian pedicle and was incorporated with the omentum from which it was undoubtedly nourished. As we could not understand how a cystic ovary, and one of evidently recent growth, could be growing from the omentum we sent the tumour to the Clinical Research Association with a note explaining the circumstances. I regret that I cannot find the note which Mr. J. H. Targett kindly wrote to me, but it was absolutely positive as to the tumour being ovarian. Fourthly, we imagined that we discovered the missing ovary at the examination after death and if it was not an ovary I do not know what it could have been that we found. *Fifthly*, the patient's death. What caused it? I have never seen anyone better than she was on the morning after the operation and she continued so until dinner-time. I was sent for at about 3 P.M. as she was thought to be dying from hæmorrhage. Dying she certainly was, but neither her pulse nor her aspect suggested hæmorrhage to my mind and moreover the temperature was rising. I can think of no other explanation than an acute toxæmia, and Mr. Targett corroborated this by saying that he knew of other cases of death from acute toxæmia after operation for tuberculous peritonitis.

I recall a case which I think resembles this one, in which I went into the country to operate for intestinal obstruction on a healthy-looking girl, who, in spite of four or five days' vomiting and obstruction, looked well and had a good pulse of not much over 70. On opening the abdomen we were surprised to find a tuberculous peritonitis with a recent adhesion obstructing the ileum close to the cæcum. The adhesion was easily dealt with and the abdomen was closed. The operation was simple and brief and I was much surprised to hear that she had suddenly collapsed and died the same night. I thought at the time that she must have died from poisoning by some fæcal toxins formed in the paralysed intestine and I regretted that I had not made a temporary artificial anus. I am now inclined to class it with the present case and to think that the toxin which killed her was formed in the tuberculous peritoneum.

GLASGOW WESTERN INFIRMARY.

A CASE OF STRANGULATED HERNIA; ENTERECTOMY.

(Under the care of Dr. DUNCAN MACARTNEY.)

THE expediency of primary enterectomy in cases of gangrene of strangulated intestine must depend chiefly on the condition of the patient. If his general state is such as to hold out any reasonable hope of his not succumbing under the increase in the length of the operation, primary resection is distinctly preferable, as the patient is spared the danger of the second operation and the duration of confinement to bed is materially shortened.

A youth, aged 19 years, was admitted into Ward 11 of the Glasgow Western Infirmary on April 21st, 1901, suffering from symptoms of strangulated hernia. He had been quite well till the night of the 17th when he felt pain in the abdomen. This pain gradually increased and became very marked, especially in the umbilical region. On the same day vomiting began and continued until the evening of the 20th. Nothing, solid or fluid, could be kept down. A medical man was at this period called in and he advised instant removal to an infirmary. This was not complied with. Early on the morning of the 21st chloroform was given and taxis was tried but without success. The patient then consented to removal and was taken to the Western Infirmary.

On admission the patient was found to be suffering very acute pain. Since the age of five years he had been the subject of an inguinal hernia on the right side. On six different occasions that he could recall he had had trouble from the swelling, the last being about a year ago. The abdomen was distended but not markedly. The upper part of the right side of the scrotum was much swollen and the scrotum on that side extended much beyond the normal. The skin was very red over the scrotum and was painful to the touch. The tumour was very tense and the percussion note was dull. There had been of late no vomiting; the pulse was good and the patient was not collapsed. The pupils were rather contracted; he had been having morphia suppositories. The heart, lungs, and urine were normal.

At 5.30 P.M. on April 21st Dr. D. Macartney, who was acting for Dr. G. T. Beatson, operated. Chloroform was given by Dr. E. Gillespie and Dr. E. Cathcart assisted at the operation. The bowel was found to be very black but still smooth and shining. A considerable quantity of blood-stained fluid escaped from the sac. The constriction was very tight. On pulling down the bowel it was found to be ruptured at the site of strangulation. The blackened portion of the bowel, about seven inches, was removed; the mesentery was left, the incision through it being along the upper margin of the bowel; the ends were sutured direct with three sets of sutures, mucous membrane to mucous membrane, muscular and serous coats to muscular and serous coats, and a Lembert's suture through the serous coat alone over both. The bowel was put back into the abdomen and the wound was closed except just above the site of the sutured bowel. This slightly open portion was stuffed lightly with iodoform gauze and the ordinary dressings were applied. The patient had some difficulty with his breathing while he was under the anæsthetic, but on the whole he took chloroform well. Recovery was uneventful except that for a few days the temperature hardly reached normal. He had enemata of soap-and-water on the third and fourth days, and about the sixth he developed a bright rash all over his body, which Dr. Macartney attributed to the enemata. His temperature rose on this occasion but never after. He steadily improved and was dismissed on May 24th well. The wound healed without pus.

Remarks by DR. MACARTNEY.—The above report is by Dr. Gillespie, Dr. Beatson's house surgeon, to whom I am indebted for it, as also for his prompt action after receiving the case and for his careful administration of chloroform at the operation. Dr. Cathcart was my more immediate assistant in the operation and to him I feel largely indebted. Some points naturally escaped the reporter's notice and these I would supplement. It was a large hernia, and when the sac was cut through the odour was very suspicious, being slightly fæcal; the colour of the discharge, too, was almost black, which is only found in very advanced cases of strangulated hernia. In addition to bowel there was a considerable mass of omentum which was firmly attached to the bottom of the sac within the scrotum. This was ligatured in two places and incised between and the mass was left in the scrotum, where it has since shrivelled up. The stricture was very tight, more like what is found in femoral hernia by Gimbernat's ligament, and this being relieved the gangrenous portion of the bowel was found on the inner side, where this sharp edge had been in contact. In removing the bowel I used no mechanical means whatever at first. The fingers of my assistant were, however, unable to control completely the upper end of the bowel and I used Makins's clamps. The mucous membrane was united to mucous membrane with a catgut suture, continuous for four or five stitches, then tying the bight to the thread and continuing for four or five more stitches, again to interrupt, and so on. It is surprising after the mucous membranes are united how very easily the remaining two rows of sutures are inserted. The parts seem to fall in quite naturally. When dealing with the mesentery it was cut straight across and bleeding points were ligatured. No sufficient reason exists for cutting wedge-shaped segments out of the mesentery. After the bowel was united the redundant mesentery was folded on itself and fixed so by a few interrupted sutures, and continuity was established between the newly approximated portions of mesentery and the joined bowel. The bowel had given way at the point of greatest constriction; but on cutting open the removed bowel from end to end we found the mucous membrane of the most distal portion almost gangrenous. That there are two factors to take into account in the death of the bowel is evident, first, the direct pressure as caused by the strangulating agent, and secondly, the interference with the blood-supply which shows, seemingly, first in the mucous membrane at the point of greatest distension.

The operation of enterectomy of itself is by no means a very serious operation, but yet looking over the statistics the number of enterectomies that are successful is comparatively small. In strangulated hernia the number is particularly small and the reason is not far to seek. Why so many resections of bowel fail is simply that in the vast majority of cases wherein one meets with gangrenous bowel resection with or without the aid of buttons or plates is entirely a mistake. In the ordinary case, by the time that the strangulated bowel has become gangrenous, so much absorption of fœtid, feculent material has gone on that the patient is virtually dying, and to keep him on the operating table during the time which is necessary to unite the ends of the bowel either by plain suturing or by mechanical means, to shorten the process, takes from him the little chance that he has remaining. That is the common case and in such it has been my practice to open the gangrenous bowel, empty it of as much of its contents as possible, and sew the margins of the bowel to the sides of the wound. The artificial anus can be dealt with later. But the exceptional cases are such as the one reported, where the patient still has a good pulse and where not too many days have elapsed since the strangulation, and particularly where youth is on his side. Under such conditions the surgeon may hope for a successful result.

It might be noted that in cutting away the diseased bowel the incision was made obliquely (about 20° to the axis of the tube), on the principle that, in view of after contraction effects, an ellipse the minor axis of which is that of the bowel contains more square area than a transverse section.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The Prognosis and Treatment of Cirrhotic Ascites with Special Reference to the Treatment by Laparotomy.—Metabolism in Phthisis.

A MEETING of this society was held on June 11th, Dr. F. W. PAVY, the President, being in the chair.

A letter was read from His Majesty the King according his patronage to the Royal Medical and Chirurgical Society.

The PRESIDENT referred to the reception by the King of a deputation from the Royal Medical and Chirurgical Society for the purpose of presenting an address of condolence on the death of Her late Majesty Queen Victoria. The President also reported that the roll of the Royal Medical and Chirurgical Society had been signed by the King. It had previously been signed also by Queen Victoria and William IV.

Dr. H. CAMPBELL THOMSON made a communication on the Prognosis and Treatment of cases of Ascites occurring in the course of Alcoholic Cirrhosis of the Liver with special reference to the Treatment by Laparotomy. There was, he said, at the present time a considerable diversity of opinion regarding the prognosis of cirrhosis of the liver after the appearance of ascites. He had endeavoured to collect such information from the works of others and from his own experience, and this he believed would establish the following points—(1) That ascites arising during the course of a case of alcoholic cirrhosis of the liver might be due either (*a*) directly to the cirrhosis, or (*b*) it might depend upon some condition co-existing with the cirrhosis, such as chronic peritonitis or perihepatitis. (2) That ascites when directly dependent upon the cirrhosis was almost always a fatal condition, while, on the other hand, ascites associated with cirrhosis, but not directly dependent upon it, might often be temporarily relieved and occasionally permanently cured. (3) That, under these circumstances laparotomy performed on cases of cirrhosis of the liver with ascites was only likely to be successful in those cases in which the ascites was an associated condition of the cirrhosis and not directly dependent upon it, and that if this were so it would be misleading to look upon the operation as being one for the cure of cirrhosis of the liver. It should rather be looked upon as a means for the relief of cases of ascites, some of which, although occurring in the course of cirrhosis of the liver, were not directly dependent upon it and which were amenable to treatment. (4) That, taking a series of cases diagnosed during life as "cirrhosis of the liver with ascites," there was not sufficient evidence to show that the operation possessed any definite superiority over the more simple method of tapping. The observations of various authorities on the subject were quoted, and it was shown that whereas a patient suffering from ascites directly due to cirrhosis of the liver rarely lived long enough to survive more than one tapping (the average duration of life, according to Dr. Hale White, after the enlargement of the abdomen was first noticed being only eight weeks), patients suffering from ascites due to some associated condition might survive repeated tappings and even apparently recover. The clinical course of cirrhosis of the liver might, Dr. Thomson believed, be summed up in the following way. Cases might exist for years without any ascites, or, indeed, without any definite symptoms, but during this period ascites was liable to arise from some associated condition, the most common being chronic peritonitis and perihepatitis. Ascites arising from this cause might be frequently relieved, and occasionally it eventually entirely disappeared, and the patient then returned to his former state of latent cirrhosis without any ascites. As time went on the cirrhosis progressed until frequently the cirrhosis itself gave rise to ascites, for which tapping was of no avail, and the patient succumbed a few weeks after its onset. There need not be, and frequently was not, any long interval between the first and last tapping, as the associated ascites often merged imperceptibly into that directly dependent upon the cirrhosis. Turning to the question of treatment directed to relieve the ascites, this could in most cases, Dr. Thomson believed, only be effectually done by tapping. Formerly it was advised to put off tapping as late as possible, whereas now it was generally advised to tap early. The more radical operation recently introduced by Morison and Rutherford[1] of opening the abdomen and promoting adhesions between the peritoneum, omentum, and parietes was then considered. A table of all the recorded cases was submitted and analysed. If the operation were to survive it must be shown that it possessed some distinct superiority over tapping since, notwithstanding the slight risk of abdominal explorations, it was in every way more formidable than tapping. The cases best suited for operation were those in which the ascites was only an associated condition of the cirrhosis; the presence of cirrhosis was not necessarily a contra-indication, but the further advanced the cirrhosis the less chance must there be of the operation being successful. If there was good reason to believe that active symptoms of cirrhosis had supervened and that the ascites was directly dependent upon the cirrhosis the operation should not be undertaken. There was, of course, often great difficulty in deciding whether the cirrhosis was still latent, and to this end the most careful attention must be given to the general condition of the patient. Errors would be further eliminated by only selecting such cases for operation which had been tapped several times.—Dr. F. PARKES WEBER mentioned that the specific gravity of the fluid withdrawn by paracentesis of the abdomen was often not ascertained, but that it ought always to be, and in regard to the point now under consideration it might furnish very serviceable information. If the specific gravity were high (say, up to 1020 or nearly so) there was probably some inflammation present. In a case of cirrhosis which he (Dr. Weber) had observed the abdomen had been twice tapped and the specific gravity of the fluid withdrawn was noted as 1020. No further tapping was required. The post-mortem examination, six years later, proved that besides cirrhosis of the liver there had been perihepatitis and perisplenitis. In such cases, if a laparotomy were performed, the localised inflammation between the liver and diaphragm or about the spleen might have escaped notice and the cure of the ascites would then be set down as due to the operation. When peritoneal effusion occurred early in cases of cirrhosis the liver generally showed obvious enlargement, and the effusion was as often induced by a non-suppurative perisplenitis as by any peritonitis localised about the liver. Temporary cardiac weakness should likewise be mentioned as a possible cause of temporary ascites in cases of hepatic cirrhosis. Like Dr. Campbell Thomson and some others, Dr. Weber thought that laparotomy was not likely to give good results excepting in cases in which the liver was large, or at all events by clinical examination appeared to be large. In many of these cases an equally good result would be obtained by a few tappings, sometimes followed by the application of pressure to the abdomen, as recommended by Dr. Alexander Morison for ascites due to various causes.—Dr. HALE WHITE referred to cases of cirrhosis of the liver with ascites which he had recorded 10 years before, and he was glad to find that Dr. Campbell Thomson had arrived at the same conclusions. All the cases he (Dr. White) had since seen tended to support these conclusions. Referring to the pathology of cirrhotic ascites, a little thought showed that it was not due merely to pressure on the venous radicals of the portal vein, and ligature of that vein did not produce ascites. Cirrhosis of the liver might be compared to granular kidney. Both lesions were only part of a general change, as witnessed by the onset of swelling of the feet in some cases before the ascites, and the termination by coma in both diseases. The ascites was probably due mostly to some associated peritonitis. When investigating a number of cases which proved, post mortem, to have cirrhosis of the liver he had found that quite half of them had never had any symptoms attributable to that condition during life. It was the same in granular kidney.—Dr. CAMPBELL THOMSON, in replying, dwelt on the early occurrence of swelling of the feet before the abdominal swelling as a valuable aid to the diagnosis of cirrhosis of the liver.

[1] Brit. Med. Jour., Sept. 19th, 1896.

Dr. FRANCIS W. GOODBODY, Dr. NOEL D. BARDSWELL, and Mr. J. E. CHAPMAN made a communication on Metabolism in Phthisis Owing to the different opinions held by various observers as to the efficiency of treating tuberculous diseases, and more especially pulmonary tuberculosis, by over-feeding, it had occurred to them to carry out some researches as to the effect of increased feeding on the metabolism of patients suffering from this disease. For this purpose cases of the disease of varying severity were selected, and after their metabolism on the ordinary hospital diet had been determined the diet was increased in various ways in order to ascertain what was the maximum they could take without causing too great a strain on the organism. Special attention was devoted to determining what number of calories per kilogramme body weight was the most suitable, as this was the easiest way of determining a suitable diet Having ascertained the highest-known weight of the patient a calculation was made as to what number of calories he would require in a healthy condition. From this it was comparatively easy to order a diet containing a sufficient number of calories to ensure that a system of over-feeding was carried out. It was difficult to see what benefit a patient could obtain from a system of "cramming," as the strain on the organism must be very excessive The researches were made at the Brompton Hospital upon cases selected by Dr. Kingston Fowler. The estimations were made at the laboratory of University College. The first series of experiments were designed to ascertain the normal metabolism of certain healthy individuals who were placed on diets containing from 60 to 80 calories per kilogramme body weight. These excessive diets were taken with great difficulty, and the condition of the patients altered considerably for the worse, although an increase in weight (from two to three kilogrammes) was noticed. For some days after the termination of the experiment they suffered considerably from mucous colitis and did not regain their normal condition for from two to three weeks In tuberculous diseases, in contra distinction to the normal individuals, patients suffering from pulmonary tuberculosis stood a markedly increased diet very well and did not suffer nearly so much from anorexia or dyspepsia. The number of calories per kilogramme body weight which gave the best results was between 50 and 70, any increase above the latter number being quickly followed by symptoms of inability to take the diet, and in some cases vomiting occurred. When more than 70 calories per kilogramme body weight were taken there was a decided increase in weight during the period, but in no case was an adult patient so well at the termination of the period. In the cases suffering from the more advanced stages of the disease more satisfactory results were obtained on diets containing about 70 calories per kilogramme, as on these diets there was a considerable retention of nitrogen in the body together with a comparatively small tax on the digestive organs. In cases which were not so advanced a diet containing about 60 calories per kilogramme gave better results as regards the absorption and retention of nitrogen than larger ones. The average quantity of urine excreted was low in comparison with the amount of fluid taken, even when there were no noticeable night-sweats, and the quantity did not increase proportionately to the increase in the quantity of fluids. In comparison with the quantity of nitrogen given in the food the excretion of total nitrogen in the urine was very low in the worst cases and increased markedly as the condition of the lesions improved. The proportion of this substance excreted in the form of urea was much below the normal in bad cases; it also fell when very large diets were given. Notwithstanding the fact that a considerable quantity of proteid was given in the diet the excretion of uric acid did not increase markedly except in cases complicated by continuous fever. On attempting to "cram" the quantity of ammonia increased considerably, pointing to diminished alkalinity of the blood. As had already been noted by Russian observers, the authors of the paper found that the quantity of phosphoric acid excreted in this disease was very small, in some cases being less than one gramme per diem, while in cases with a considerable degree of arrest the excretion rose to 2 5 and 3 grammes.' The rate of absorption of nitrogen was, on the whole, below the normal, the more so the greater the severity of the disease. On increasing the amount of proteid given there was a lessened absorption of nitrogen per cent., so that on large diets the waste of food was very considerable. The average rate of absorption of fats was extremely good in all the cases, averaging about 98 per cent, thus confirming the clinical observation that fat-containing foods were very well borne in pulmonary tuberculosis. In the most advanced cases of the disease under observation the most suitable diet was found to consist of 129 87 grammes proteids, 135 05 grammes fats, and 225 56 grammes carbohydrates. The conclusions arrived at were: 1. Both clinically and experimentally tuberculous patients showed very satisfactory results on their diet being increased slightly above the original, and it was evident that the state of the appetite gave too low an estimate of the requirements, as the original diets were of their own selection as regards quantity. 2. Comparatively large diets were well borne by those who were much below their normal weights, but not so well supported by—nor were such good results obtained in—patients up to their normal weight and with arrested disease. 3 In all cases very large diets gave unsatisfactory results, as the gain in weight was at the expense of the general health, as indicated by the failure of appetite, marked digestive disturbance, and increased intestinal putrefaction. 4. Moderately large diets gave the best results, and could probably have been continued for an indefinite period 5. The assimilation and absorption of nitrogen was good on the whole, even in cases with high pyrexia The absorption of fats was excellent, although very large quantities were given. 6. The patients complained least of discomfort on the diets which gave the best results experimentally, and the onset of severe dyspeptic trouble coincided with deterioration in the experimental results. 7. In cases in which the disease was becoming quiescent and the patient was approaching his normal weight it was advisable to diminish the quantity of food; but even at this period a more substantial diet was necessary than when in health.—Dr. BARDSWELL remarked that moderate quantities of food gave the best results. The diet in any given case was best fixed by considering the amount of weight the patient was below his maximum and the range of the pyrexia as representing the activity of the disease Further, if a patient put on one pound per week the lungs did better than a more rapid increase He was much opposed to "cramming"—Mr. CHAPMAN remarked that the diets as shown on the charts exhibited had been calculated without certain extras The diets were worked out at 50 calories per kilogramme —The PRESIDENT complimented the authors on their communication and remarked on the value of their researches in the sanatorium treatment of phthisis as being based upon a rational chemical foundation.—Dr. HALE WHITE had made some similar observations on a patient under the Weir Mitchell treatment and in the main had come to the same conclusions The patient had taken very large quantities of food. The fat had all been absorbed excepting about 3 or 4 per cent He had never succeeded in attaining a nitrogenous equilibrium and suggested, in order to account for the nitrogenous deficit, that possibly it was stored up in the tissues in some form other than proteid. He remarked on the laborious nature of such investigations —Dr HORTON SMITH asked if it was possible to give some simpler rules for the construction of a dietary.—Professor VAUGHAN HARLEY remarked on the laborious nature of such inquiries. They opened a new domain in medicine. The nitrogenous deficit was partly due, perhaps, to "cheating" by the patient A deficit of three grammes was well within experimental error. Too rapid an increase caused considerable upset and what was to be aimed at was a steady increase in weight. The number of calories per kilogramme could be based on the difference between the present and the highest weight of the individual —Dr. GOODBODY, in reply, referring to the difficulty of obtaining nitrogenous equilibrium, said that the six patients under observation during four weeks gave 22 different periods for investigation, and of these they had succeeded in obtaining nitrogenous equilibrium in three instances. There was no easy means of obtaining accurate information, though the estimation of urea gave a certain amount of information. The best method was to estimate the total nitrogen in the urine and fæces.

OBSTETRICAL SOCIETY OF LONDON.

Fibroid Tumours complicating Pregnancy and Labour.—Exhibition of Specimens.

A MEETING of this society was held on June 5th, at 20, Hanover-square, W., Dr. PETER HORROCKS, the President, being in the chair.

Dr. ARCHIBALD DONALD read a paper on Fibroid Tumours complicating Pregnancy and Labour. He said that he had come to the conclusion that in the majority of instances neither pregnancy nor labour was seriously influenced by these tumours, but that in a small proportion of cases the danger to mother and child was greatly increased. The risks during pregnancy might be summed up as follows: (1) rapid increase in size of the tumour, causing severe pain and great distress; (2) incarceration of the tumour in the pelvis; (3) serious pressure on the bladder; (4) degeneration of the tumour through diminished nutrition; (5) excessive rotation of the pregnant uterus; and (6) abortion or premature labour as a result of pressure or of submucous development of the fibroid. Abortion or labour might be complicated (1) by obstruction of the natural passages; (2) by malpresentations; (3) by retention of the placenta or membranes; and (4) by extrusion of the tumour during labour. During the puerperium the presence of a uterine fibroid rendered septic infection more likely. The treatment of this complication of pregnancy and labour was then discussed. Two main groups of cases were recognised: (1) those in which pregnancy was allowed to take its course until full term or until the child was viable; and (2) those in which it was necessary to interfere in the earlier months. In the great majority of cases it was better to leave matters alone until term. If the tumour was located in the pelvis the treatment in each case must be settled by a careful examination—if necessary under an anæsthetic. Cæsarean section was preferable to delivery by the natural passages if the latter involved the employment of much force. He gave notes of a case in which there was rapid enlargement of the fibroid during the first three months of pregnancy but in which the condition of the patient was fairly good and in which the pregnancy was allowed to go on until nearly term. The occurrence of albuminuria and rapid deterioration in the patient's health then rendered interference necessary. It was ascertained on examination under an anæsthetic that delivery by the natural passages would be attended with great difficulty. Cæsarean section and subsequent hysterectomy were successfully performed. He then discussed the treatment in the earlier months, when interference was necessary, under the heads of (1) induction of abortion; (2) hysterectomy; and (3) myomectomy. In Dr. Donald's opinion the induction of abortion ought to be abandoned. Notes were given of a case in which the patient was admitted to hospital on account of a rapidly growing fibroid. Spontaneous abortion occurred, but the placenta was retained and had to be removed artificially. In spite of the most careful aseptic precautions septic infection occurred and a serious illness resulted. Some months later the tumour was removed by abdominal myomectomy. Dr. Donald described three cases of abdominal hysterectomy for rapidly growing fibroids in the early months of pregnancy, but he advocated a preliminary myomectomy whenever it was possible, as by this measure the life of the child might be saved. In all cases of subperitoneal pedunculated fibroids the tumour ought to be removed during pregnancy. When the tumour was more sessile and operation was required in the earlier months, it was best to enucleate the tumour and stitch up the gap in the uterine wall. If, however, the raw surface was too extensive, or if it was close to the uterine cavity, or if hæmorrhage was difficult to control, the operation ought to be terminated by hysterectomy.

Mr. ALBAN DORAN spoke of his own case of pregnant fibroid uterus successfully removed at the fifth month, reported in THE LANCET of March 2nd, p. 621, and he exhibited the specimen. There was a large fibroid outgrowth on the fundus which, as is usually the case, could in itself have hardly prejudiced either pregnancy or labour. There was a second large outgrowth springing from the posterior aspect of the lower segment and incarcerated in the pelvis which pressed the cervix against the pubes. Emptying the uterus through the vagina was impossible, and on account of the severity of the pressure symptoms it was not advisable to wait till term and then perform Cæsarean section. Myomectomy was impracticable on account of the position of the fibroid, and in this case an attempt to push the fibroid out of the pelvis would have involved great risk of rupture of the soft uterus which would have been squeezed between the two hard tumours. There was no course left but retro-peritoneal hysterectomy which proved very satisfactory.

Dr. WILLIAM DUNCAN could not agree with Dr. Donald that pregnancy and labour are only seriously influenced in a small proportion of cases by the presence of fibroids. He mentioned cases in which he had met with serious obstruction in the pelvis even after abortion had been induced, also rupture of the uterus during pregnancy with fatal result, and he had a case some years back under his care in the Middlesex Hospital where the patient was waiting until full term had arrived in order that he might perform Cæsarean section but who died from cerebral apoplexy whilst resting quietly in bed. With regard to subperitoneal fibroids he could not agree with Dr. Donald that "in all cases they should be removed during pregnancy," for unless a fibroid of this kind were impacted in the pelvis it should be left severely alone and the pregnancy and labour would proceed naturally. With regard to interstitial or submucous fibroids the nearer the cervix they were situated the greater the danger; and in these cases he thought the best interests of the mother were provided for by emptying the uterus if the pregnancy were in the early months. If, however, the tumour obstructed delivery it was better to perform Cæsarean section and then remove the uterus and the fibroid than to attempt delivery by craniotomy.

Dr. G. E. HERMAN said that many valuable papers had been written on pregnancy with fibroids. Dr. Donald's paper was the first in which pregnancy with fibroids had been adequately treated in the light of modern surgery. In all his main points he agreed with Dr. Donald. He was not convinced of the effect of fibroids in causing abortion. Dr. Donald had quoted figures which were supposed to show that abortion was frequent—those of Kelly who put the frequency at 25 per cent. and those of Lefour, which came to about 20 per cent. But 20 per cent. was about the normal frequency of abortions to labours at term. That fibroids often caused premature labour he thought was beyond doubt. The danger of pregnancy with fibroids depended more upon the situation of the growth than upon anything else. Fibroids situated above the lower segment of the uterus, unless very large, commonly caused no trouble in pregnancy or labour. He agreed with the preceding speaker that it was not necessary to remove every small subperitoneal fibroid that co-existed with pregnancy. If a fibroid or fibroids were situated in the lower segment of the uterus delivery might be obstructed by them. In such cases he (Dr. Herman) thought that the essential condition for the best treatment was to decide before labour, or quite early in labour, whether or not the tumour would obstruct delivery, and if it was judged that delivery would be obstructed to perform Cæsarean section or myomectomy, whichever seemed best, before the patient had been exhausted by prolonged labour. In deciding between myomectomy and hysterectomy he thought that in a patient so old that further pregnancy was not likely, hysterectomy was to be preferred as being safer than myomectomy.

After some remarks by Dr. HENRY BRIGGS,

Mr. J. BLAND SUTTON observed that next to pregnancy it seemed probable that "fibroids" were one of the commonest conditions to which a woman's uterus was liable, and it was equally certain that fibroids and pregnancy often co-existed and that the two conditions had no baneful effect on each other. It was also equally certain that occasionally the co-existence of fibroids and pregnancy was fraught with great danger to the life of the mother, and the treatment of these cases had often been a matter of grave concern to those who undertook to superintend delivery. Mr. Bland-Sutton wished particularly to draw attention to the fact that in many instances in which hysterectomy had been performed in the early months of pregnancy for this complication the operation had been undertaken on the ground that the fibroids had "recently been growing quickly," but when the uterus had been removed the operator found that the presumed rapid growth was due to the associated pregnancy. He was interested in the successful enucleation of fibroids from the pregnant uterus. In one case in which he had found it necessary to perform this operation at the fourth month the uterus was quite smooth and no other tumours were seen or felt. The pregnancy went to term and a fine boy was born without difficulty, but the uterus was tuberose with fibroids, and to add to the disappointment the child was found to have an imperforate pharynx. Although abdominal enucleation of fibroids could be performed with less risk than hysterectomy it was very rarely necessary in pregnancy and very unsatisfactory, as in a large proportion of cases other fibroids arose in the uterus. Thirty years ago Sir Spencer Wells startled the obstetrical world by urging that unilateral ovariotomy was practicable and justifiable during pregnancy. About 15 years later it was proved that double ovariotomy could be successfully performed during pregnancy and without disturbing the fœtus, and in 1901 the society received with equanimity the fact that a fibroid might be enucleated from the wall of a gravid uterus without interference with the pregnancy, the mother going safely through her confinement and gaining a vigorous child. Surely this might be regarded as a triumph of modern surgery.

Dr. A. H. N. LEWERS said that when a fibroid tumour complicated pregnancy much depended on the exact situation of the tumour. In cases like that exemplified by Mr. Doran's specimen where the tumour was situated low down it offered an insuperable obstacle to the passage of the child and necessitated Cæsarean section. In cases, also, where a patient already the subject of a large uterine fibroid became pregnant, even though the fibroid was situated in the upper part of the uterus, abdominal hysterectomy might be needed in the early months on account of the distress caused by the extra enlargement of the uterus. Such cases were, however, in his experience quite exceptional. He had seen a considerable number of cases of pregnancy complicated by fibroid tumours in which the patients passed through pregnancy, labour, and the puerperium normally. In Dr. Lewers's opinion it would be a pity if the impression were to become general that when fibroid tumours complicated pregnancy abdominal hysterectomy or myomectomy was generally required

Dr. HERBERT SPENCER agreed with most of the recommendations in the paper. He was especially glad to hear that Dr. Donald condemned the induction of abortion. In cases where fibroids occupied the cervix or the lower segment of the uterus that operation was very dangerous owing to the rigidity of the tissues and the difficulty or impossibility of completely emptying the uterus. Though he had never performed the operation himself he had known it to terminate fatally in skilful hands when every precaution was adopted, and he thought the operation should not be performed. He agreed with Dr. Lewers in advocating a more conservative treatment of many of these cases. Fibroids implicating pregnancy were fairly common. At University College Hospital, where about 2500 cases of labour were attended annually, he had seen a considerable number of cases of pregnancy and labour complicated with fibroid tumours, but he had never met with a death from the complication and had only once had to perform Cæsarean section and to remove the uterus. He had seen cases in which it was expected that fibroids in the lower segment would interfere with the passage of the child, but when labour set in the tumours were drawn up out of the way and delivery was safely effected. Dr. Spencer was of opinion that hysterectomy in the early months of pregnancy was far too frequently performed. He would treat the severe pain which was often present by the usual medicinal remedies and would permit a living child to be born either naturally or by operation. He thought that the statement that all *subperitoneal pedunculated fibroids* ought to be removed during pregnancy was too absolute, and he wished (though this remark did not apply to Dr. Donald's paper) to enter an emphatic protest against the removal on account of pain of small sessile corporeal fibroids by enucleation through the abdomen during pregnancy, an operation which was by no means free from immediate and remote risks, which sometimes necessitated hysterectomy on account of hæmorrhage, and which probably left in the uterus growths which might require a subsequent radical operation.

Mr. A. C. BUTLER-SMYTHE quite agreed with the remarks made by Dr. Spencer and was glad to join in the protest against indiscriminate operating. Personally he was much obliged to Dr. Donald for teaching him that large myomata could be safely removed from the pregnant uterus, but he could state that in his experience there were instances where living children were delivered without resorting to abdominal operations. He recognised the necessity for operating in the specimens shown, but thought that there were many cases in which the fibroid might well be left alone.

The PRESIDENT quite disagreed with those who alleged that fibroid tumours of the uterus did not cause miscarriage. It was true that a woman might have fibroids and not miscarry. He had known a patient to be delivered of a full-term child whilst suffering from a sub-peritoneal fibroid as big as the pregnant uterus at full term. It was in the subperitoneal variety that miscarriages were not the rule. Small fibroids might exist without causing a miscarriage, but his own experience proved that when there was a fibroid tumour of the size of a cocoa-nut in the wall of the uterus it almost invariably caused miscarriage. Many such patients came with a history of repeated miscarriages, occurring generally at about the same period of gestation—namely, the third or fourth month, as if at that time the further growth of the ovum was interfered with by the tumour, and hence the expulsion of the contents of the uterus. Whilst it was true that with modern aseptic methods the mortality in hysterectomy had been greatly reduced it was equally true that the mortality in induction of miscarriage had also been greatly reduced. Nevertheless, aseptic methods had not eliminated one danger in the induction of miscarriage for fibroids, and that was hæmorrhage. This danger was considerable, because even after the escape of the liquor amnii it was often impossible, owing to the increased length and tortuosity of the canal, to reach with the finger so as to peel off the whole of the placenta. Very probably in every one of the cases described by Dr. Donald the operations were necessary, because the tumours were large and caused great obstruction. But he could not agree with the deduction that in early pregnancy with fibroids abdominal section should be performed in all cases. On the contrary, many cases, perhaps the majority, might well be left alone with a reasonable hope that all would go well. As in other diseases, each case must be judged on its own merits.

Dr. DONALD, in reply, said that many of the criticisms which had been made were due to a misunderstanding. Many of the speakers had objected to his advocacy of the removal of pedunculated sub-serous fibroids during pregnancy. The kind of tumour which he had in mind in giving this advice was a hard fibroid of fair size and with a pedicle sufficiently long and narrow to allow of considerable range of movement. The risk of removing such a tumour during pregnancy was no greater than was that of ovariotomy. On the other hand, there was great risk during pregnancy and labour and the subsequent involution of the uterus of these tumours being rotated so that their nutrition was interfered with. The only kind of case in which the induction of abortion could be entertained was one in which the delivery of a mature fœtus was manifestly impossible owing to the blocking of the pelvis by one or more fibroid tumours. In such a case the canal was generally elongated and tortuous, and there was as much risk in this method of treatment as in an abdominal operation. Morever, in any case where such conditions existed, even if the uterine cavity were safely emptied, a subsequent operation for the removal of the tumour would almost certainly be required.

The following specimens were exhibited:—

Dr. DONALD (for Dr. W. E. FOTHERGILL): A Decidual Uterine Cast of seven weeks' growth expelled with an ovum of about five days' growth, with microscopical section. This specimen was referred to a sub-committee for report.

Dr. H. R. ANDREWS: Two cases of Fœtal Ascites and Œdema.

Mr. STANLEY BOYD (introduced by Dr. AMAND ROUTH): An unusual case of Suppurating Fibro-myoma of the Uterus removed by Hysterectomy.

Mr. DORAN: A Pregnant Fibroid Uterus removed in the fifth month.

The specimens were discussed by the PRESIDENT, Dr. C. J. CULLINGWORTH, Dr. DONALD, Mr. DORAN, Dr DUNCAN, Dr. T. W. EDEN, Dr. HERMAN, Dr LEWERS, Dr. ROUTH, Dr. SPENCER, Dr. T. G STEVENS, and Mr. J. H. TARGETT

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—A general meeting of this society was held at 20, Hanover-square, W., on May 31st, Dr. F. Bagshawe, the President, being in the chair.—The annual dinner took place the same evening at Limmer's Hotel when Sir William

Church, Bart., proposed the toast of "The British Balneological and Climatological Society" and Dr. Fortescue Fox, chairman of the Council, responded.—The annual conversazione was then held and Dr. Burney Yeo read an address entitled "Hepatic Inadequacy."—Dr. Symes Thompson proposed, and Dr. Douglas Kerr seconded, a vote of thanks to the lecturer.—The President showed Prints of old Hastings.—Dr. O. Begg (Bath) showed a Douche-Massage Chair.—Dr. Morgan Dockrell showed Microscopic Specimens of Skin Diseases—Dr. Glover Lyon showed a Model of an Interesting Ventilating System.—Mr. Chisholm Williams showed an apparatus for producing Electrical Currents of High Potential and High Frequency.—The Bath Corporation showed a model of the Old Roman Baths of Bath.—The Harrogate Corporation showed a mode of Combination of Douche and Needle Bath.—Dr. Cecil Musgrave (Cromer) showed views of Cromer and there were other interesting exhibits by Messrs. Negretti and Zambra (Meteorological Instruments), Messrs. Callard and Co. (Dietetic Preparations), Messrs. John Bale and Sons (Books), Messrs. Oppenheimer and Frank Rogers (Drugs), and Mr. Alfred Cox (Instruments). The society now numbers 360 Fellows.

WIGAN MEDICAL SOCIETY. — An ordinary meeting of this society was held on June 6th; there was a good attendance of members.—The President (Mr. W. Latham) read his presidential address on Minor Points in the Treatment of Surgical Diseases of Children.—The address was a practical and interesting one and lead to a hearty vote of thanks from the members, Dr. White, Dr. Benson, Dr. W. R. Dix, Mr. McElligott, Mr. Greene, and the honorary secretary speaking to various points raised in the paper.

Reviews and Notices of Books.

A Text-book of Pathology. By ALFRED STENGEL, M.D., Professor of Medicine in the University of Pennsylvania; Physician to the Philadelphia Hospital, &c. Third edition, revised. London and Philadelphia: W. B. Saunders and Co. 1900. Pp. 872, 372 illustrations. Price 21s.

THIS being the third edition of this work but few words are needed to explain its nature and scope; suffice it to say that the author has tried to present the subject of pathology in as practical a form as possible, and always from the point of view of the clinical pathologist and an admirable text-book is the result. The present edition has been thoroughly revised with the intention of bringing the subject matter up to date and amplifying the sections on Pathologic Physiology. Controversial matter has been avoided as much as possible, excepting in certain parts of the sections on General Bacteriology and on Neuropathology in which conflicting theories are properly discussed.

We consider that this text-book will be found a convenient one for students. The descriptions of the various morbid conditions are complete and comprehensive without being too long, and a good knowledge of pathology should be acquired by a careful study of the pages of this manual.

The value of the work is augmented by the many illustrations scattered through it; the majority seem to be borrowed but are not to be despised on that account. We notice a particularly good one, which is apparently original, showing the histological changes found in acute appendicitis.

It is not easy in a volume of this kind dealing with a general subject such as pathology to select any special portions for comment. The descriptions of the various forms of tumours are especially worthy of attention and the chapter on Bacteria and Diseases due to Bacteria will be found to contain a vast amount of information. We notice that in referring to the smegma bacillus the word "acid-proof" is employed—a better term than the literal translation "acid-fast," which is generally adopted.

The hæmatozoon malariæ is also well described. The chapter on Diseases of the Blood is brought fully up-to-date; this is necessary as our knowledge in this respect has been greatly added to in quite recent years. The varieties of leucocytes and the pathological changes which the red and white blood cells undergo are duly noticed, as well as the conditions included under the title of "Primary Anæmias."

The term "peptic ulcer" is used instead of "gastric ulcer"—a change which cannot be altogether accepted, as the pathology of the condition has not been satisfactorily explained. The author says: "It is admitted that they [the ulcers] are due to the action of the gastric juice upon parts of lowered vitality." This is the probable cause of the ulcers, but the controversy on their etiology still wages, and it would have been better to retain the old term "gastric ulcer" until the pathology has been more definitely determined.

The chapter on Diseases of the Bones is well worthy of notice; an excellent coloured plate showing the epiphyseal junction in congenital syphilis also claims attention.

We congratulate Professor Stengel on having produced a capital manual on pathology.

A Clinical Treatise on Fractures. By WILLIAM BARTON HOPKINS, M.D., Surgeon to the Pennsylvania Hospital and to the Orthopædic Hospital and Infirmary for Nervous Diseases, Philadelphia. Philadelphia and London: J. B. Lippincott Company. 1900. Pp. 268. Price 18s.

THE basis of this volume was a series of clinical lectures delivered by the author at the Pennsylvania Hospital and they have been revised and elaborated so as to make them a complete work. The book is written in a pleasant manner and should prove interesting reading. Obsolete methods have been omitted as unnecessary for a practical treatise, and in cases where several modes of treatment are possible the author has described that method which he has personally found to be the most simple and effective.

A valuable chapter is that recording an important series of experiments which had for their object the investigation of the actual force required to fracture adult bones. By means of various testing machines the transverse, crushing, and tensile strains were estimated. The bones experimented on were taken from the body of a strong adult mulatto, 27 years of age, who had died from an acute disease. The femur was subjected to a crushing strain of 3130 pounds before it yielded, while 1155 pounds applied transversely sufficed to fracture the bone. It is, indeed, remarkable, as the author observes, that a pressure of over half a ton applied transversely was required to break the femur. When the patella was subjected to a tensile strain the bone did not break, but the ligamentum patellæ was ruptured about its middle at 1845 pounds. Dr. Hopkins appears to be surprised at this, but it has long been recognised that mere traction never breaks the patella; and if the knee is straight when the quadriceps contracts either the tendon of the quadriceps or the patellar ligament will give way. If, however, the knee is bent the patella touches the femur on only a very narrow surface so that the quadriceps and the ligament are pulling on the bone with less than a right angle between their directions. When the patella gives way under these circumstances the fracture can in no sense be ascribed to the action of tensile forces. This fact, indeed, the author recognises to some extent, but he does not attribute to the flexed position of the knee the importance it deserves.

Many useful skiagrams illustrate the positions of the fragments in fractures and must materially assist the student. The treatment advocated is sound and modern. In the description of the methods of fixation of compound fractures the author describes an ingenious "rack" which he has devised for holding the fragments of the bone while they are being sawn and drilled for an ivory screw, and in certain cases such an apparatus would prove very useful.

The Extra Pharmacopœia By WILLIAM MARTINDALE, F.L.S., F.C.S., late President and Examiner of the Pharmaceutical Society; and W. WYNN WESTCOTT, M.B. Lond., D.P.H., H.M.'s Coroner for North East London. Tenth edition. London: H. K. Lewis. 1901. Price 10*s.* 6*d.* net. Pp. 688.

WHEN a book has reached its tenth edition and is so well known as the Extra Pharmacopœia anything that may be said by the reviewer is a mere work of *supererogation.* It *presents* a mine of information of its kind, so arranged as to be ready to hand and accessible to the reader and the busy practitioner, and it is not easy to realise the amount of labour and care which its compilation must have entailed. The authors in their preface to this edition call attention to the fact that since the publication of the last British Pharmacopœia there have been numerous additions of an official and non official kind to the subject in hand, and that they have from a pharmaceutical point of view made a careful study of these publications and also of all the current literature in order to place a fair review of the present condition of pharmacy and therapeutics before their readers. We have had the curiosity to compare this tenth edition with a copy of the fourth edition published in 1885 which we happened to have in our possession and we think that the authors of the present edition may be congratulated on having successfully accomplished their task. The work throughout bears marks of having been carefully revised. In the section headed Analytical Memoranda, for example, and comprised within the pages from 525 to 544 they have managed to compress a large amount of useful information about matters which a few years ago had relatively little significance to the ordinary medical practitioner and with which he did not therefore concern himself. And the same may be said about other points scattered here and there throughout the pages of the present volume. We need scarcely add that this edition of the Extra Pharmacopœia is a most useful little *vade mecum* and deserves its popularity.

The Practice of Medicine. By JAMES TYSON, M.D., Professor of Medicine in the University of Pennsylvania and Physician to the hospital of the University, Physician to the Philadelphia Hospital, &c. Second edition. London: Rebman, Limited. 1901. Pp. 1240. 127 Illustrations Price 24*s.*

THIS volume is intended as a text-book for practitioners and students, with special reference to diagnosis and treatment. The morbid anatomy and pathology are thus very briefly dealt with; considering the numerous excellent manuals dealing solely with these subjects this plan is a judicious one We strongly oppose the idea that "clinical medicine" and "pathology" should be separated—a successful knowledge of the former must largely be founded on the latter; but a book such as we have now before us is most valuable, both for a student to study in conjunction with other works and also to refer to when busy with his duties in the wards and out-patient rooms. In the midst of practice also a practitioner welcomes a work on medicine in which he can readily find information which will aid him in the diagnosis of disease and treatment of his patients.

In the revision called for by a second edition of this text-book opportunity has been taken to make such additions and corrections as the progress of medicine since its publication seemed to demand, and the book has been thoroughly brought up to date.

The section on Infectious Diseases is most complete The account given of the malarial fevers is well worthy of perusal and the description of the malarial organism is full and accurate. In accordance with modern views pneumonia (croupous, chronic interstitial, and broncho-pneumonia), and rheumatic fever are included under the heading of infectious fevers; but the author has acted wisely in retaining chronic articular rheumatism and muscular rheumatism under the "constitutional diseases." The present state of medical knowledge does not, in our opinion, justify an author in doing otherwise.

The sections on Diseases of the Blood and the Vascular System have naturally received considerable additions. A new feature in the more recent text books on medicine is the introduction of "blood charts" showing the variation in the number of red and white corpuscles and the proportion of hæmoglobin in the course of certain diseases. In Dr. Tyson's work we find instances of such charts in the subsections on Typhoid Fever, on Secondary Anæmia, and on Chlorosis.

The section on Diseases of the Nervous System has also been considerably enlarged.

Throughout the book the clinical descriptions are clear and full, and the methods of treatment described are those generally recognised as being the most modern and satisfactory. We congratulate Dr. Tyson on having produced a readable and instructive manual.

Human Placentation: An Account of the Changes in the Uterine Mucosa and in the Attached Fœtal Structures during Pregnancy By J. CLARENCE WEBSTER, B.A., M.D., F.R.C.P., F.R.S. Edin With 233 Illustrations Chicago: W. T. Keener and Co. 1901. 8vo. Pp 120. Price $3 75 net

AS Professor Webster remarks in his introduction, there is no department of embryology in which greater differences of opinion exist than in that which is the subject of this work. His own observations, based as they are upon an examination of the placenta at all periods of pregnancy and upon numerous early abortions, are of great interest and value, and will do much to settle many of the disputed points in regard to the anatomy of the early placenta. The book represents the outcome of some 11 years' work, and has the advantage of placing before the English reader full details of the extremely interesting specimens of early pregnancy recently described by Leopold and Peters. In *the latter specimen* the pregnancy was probably not more than five or six days old, and as the appearances were very fully and completely described we are at last in possession of some trustworthy information as to the changes that occur in the decidua in the very earliest days of gestation.

In considering the decidua vera the author is of opinion that the decidual cells are undoubtedly derived from pre-existing embryonic cellular elements He is unable to confirm Eden's view that the occurrence of hæmorrhages into the early decidua vera is an essential change, nor can he find any evidence of the development of new glands Peters's view as to the origin of the decidua reflexa by the sinking of the ovum into the mucosa and the lateral excavation of the latter is accepted. The absence of any epithelium upon the inner surface of the reflexa and its irregular outline are in favour of this explanation. The occurrence of degenerative changes in the decidua reflexa, as early as the sixth week is a matter of much interest and the fact that when a reflexal placenta is formed these degenerative processes do not occur until much later is of importance in regard to the possible causation of such degeneration.

Chapter V. upon the Early Relation between the Ovum and the Decidua is one of great interest. The work of Peters and Hubert is fully considered and a good account is given of the development of the trophoblast from the primitive epiblast.

its subsequent vacuolation, and the development of maternal blood spaces in its meshes. It must be a source of satisfaction to Professor Webster to find how fully the views expressed by him in his book on "Ectopic Pregnancy" as to the nature and formation of the trophoblast have been confirmed by subsequent observers. As to the probable functions of the early epiblastic proliferation the author suggests that it serves to fix the ovum; the trabeculæ form path-finders for the future villi, and perform the important function of absorbing nutrition for the early ovum.

There are very many points of great interest described in connexion with the development of the placenta, its shedding, and its phylogeny and the plane of separation of the ovum, for which we must refer our readers to the work itself. The book is very fully illustrated with numerous drawings and micro-photographs. The latter have all the defects that usually accompany their reproduction. It is a pity that the author has not adopted a uniform system of lettering, as in that way the labour of examining the numerous illustrations would have been materially lightened. The whole book is the outcome of some very good work and it is encouraging to find that we have at least one English worker who is able to dispute the supremacy of the Teutonic host who have so far mainly monopolised this field of research.

LIBRARY TABLE.

Atlas und Grundriss der Speciellen Pathologischen Histologie. (Atlas and Manual of Pathological Histology.) Von Privat-Docent Dr. HERMANN DURCK, Assistant in the Pathological Institute in Munich. Vol. II. Munich: J. F. Lehmann. 1901.—This forms the twenty-first volume of the excellent series of "hand atlases" published by J. F. Lehmann. It comprises descriptions of the histology of the liver, urinary organs, reproductive organs, the nervous system, skin, muscles, and bones. The work maintains the high standard of its predecessors. The plates are most beautifully reproduced and are accurate representations of the microscopic structure of the various organs concerned and the changes produced by disease. Amongst the plates devoted to affections of the liver a plate representing the pathological histology of acute yellow atrophy is noteworthy, as are also plates showing recent and old gummata in the liver. Amongst the many other excellent plates we find illustrations of the following conditions: the kidney in acute leukæmia, embolic tuberculosis of the kidney, "diphtheritic cystitis," tuberculosis of the prostate, testicle showing gummata, tuberculous salpingitis, syphilitic spinal pachymeningitis, tuberculous and syphilitic lepto-meningitis, multiple sclerosis, pigmentation of the skin in Addison's disease, and osteomalacia. We can only once more express our unbounded admiration as to the manner in which these volumes are published and the plates reproduced.

The Church of Humanity. By DAVID CHRISTIE MURRAY. London: Chatto and Windus. 1901. Pp. 318. Price 6*s.*—This is the history of one John Manger who from being a clown in a travelling canvas theatre and more or less of a dipsomaniac became immersed, converted, and carried away in a religious movement. Inspired by a passion to be of service to mankind he became the founder of a Church. John Manger was a man of strong emotional nature without any education or pretence, but endowed with oratorical powers and a melodramatical style of preaching of no mean kind, and if he was a religious fanatic he is nevertheless represented as thoroughly sincere and dominated by such a passionate belief in the truth of what he was advocating as to make him for the time being inspired. There is no lack of sensational and exciting incident introduced into his history and career from its beginning to its close, what with hypnotism, the tragic history of his marriage, and all that it led to. It is powerfully written and the characters are strongly drawn, and the description of the people among whom John Manger lived, moved, and had his being is, we doubt not, true to life and well done, but we find ourselves asking whether the impressions created by reading literature of this sort be of a wholesome nature. The parts descriptive of Mrs. Toombey, the widowed occupant of a travelling van, and of her wedding with Mr. Grimes, and of Mrs. Manger's interview with her husband's business brother in the church transactions when calling upon him to produce his accounts are excellent as well as amusing.

BOLINGBROKE HOSPITAL, WANDSWORTH COMMON.

THE Lord Mayor, accompanied by the Lady Mayoress, the Sheriffs, and other city officials, visited Wandsworth on June 8th to lay the memorial-stone of the new Victoria wing of the Bolingbroke Hospital, Wandsworth Common. The civic party was met some distance from the hospital by a procession of trade and friendly societies, which accompanied it to the site prepared for the laying of the stone. The Mayor was received at the hospital by Canon Erskine Clarke and other governors.

Canon ERSKINE CLARKE, addressing the Lord Mayor, said that in the name of the governors of the hospital he had the honour to ask his lordship to lay the corner-stone of this new wing which had been given the name of their late good queen. It was called a wing and it would be a wing of the old house, but it really was much more. It was the first part of a great hospital with 150 beds. The new wing would be used as an out-patient department. The difficulty of dealing with out-patients who were able to pay for medical treatment had been overcome, thanks to the suggestion of Mr. Lyster, the medical superintendent, and no out-patient was received except with a certificate from a duly qualified medical man. He pointed out that the population of Battersea had grown considerably during the last 25 years and he dwelt upon the necessity for the hospital which was four miles distant from the nearest general hospital. The governors had been greatly encouraged in their efforts to carry on the hospital by the loyal support of the industrial classes who had contributed £900 towards the hospital.

Prayer was then offered by the Bishop of Southwark and the Lord Mayor performed the ceremony of laying the memorial stone. The Lady Mayoress received a number of purses, the first donor being a baby, a patient from the hospital carried by one of the nurses. A vote of thanks to the Lady Mayoress and the Purse-holders, moved by Mr. Percy Thornton, M.P., and seconded by Mr. H. Kimber, M.P., and also to the Lord Mayor, moved by Mr. William Davies, J.P., L.C.C. (Mayor of Battersea), and seconded by Mr. J. Lidiard, J.P. (Mayor of Wandsworth), concluded the proceedings.

DOWNDERRY, a seaside resort on the Cornish coast, was *en fête* on June 5th, when the new water-supply was formally opened. The supply is derived from Deviock by means of springs and reservoirs, the cost being estimated at about £1400. Downderry has also an efficient system of drainage which was completed in October, 1900.

THE LIVINGSTONE EXHIBITION.—The second Livingstone Exhibition, under the patronage of Princess Christian, which is practically a Travellers' Health Exhibition, will be held in the Westminster Town Hall from June 18th to 21st. A representative display will be made of travellers' requisites by leading firms engaged in the sale or manufacture of such goods, and lectures will be delivered on a variety of subjects relating to health and travel. There will also be a valuable loan collection, including a number of Livingstone relics, one of which is the section of the tree containing the inscription which originally marked the place where Livingstone's heart lies buried and which is lent by the Royal Geographical Society.

New Inventions.

PORTABLE SURGICAL MOTOR

KNOWING the want felt by surgeons for a good form of motor which can be carried about to private operations we send a description of one used by us It has been constructed by Messrs Mayer and Meltzer of Great Portland street who have spent much time in perfecting the various details The 16 volt accumulator is of a sealed type, having a capacity of 18 ampère hours and it weighs about 34 pounds The motor is of the type known as the "D" pattern, so called on account of the shape of the field magnet The armature is a gramme ring and is attached directly to the shaft which carries the cable thus acting the part of a fly wheel It weighs about 15 pounds and is mounted on a gun metal turn table which enables it to rotate and to follow the movements of the operator The turn table is mounted on a platform at each corner of which are sockets and similar sockets are attached to the steel frame which surrounds the accumulator Into these sockets steel tubes are fitted which form a rigid stand at a convenient height The accumulator acts as a secure base for the motor when in action The metal cable is directly attached to the central shaft of the motor and is covered with a flexible metal tube which can be boiled The hand piece is attached to the cable by means of a left-handed screw It is perfectly plain in design and has no corners for the accumulation of septic matter The drills, saws, and other tools are held in position by a spring clutch acting in a groove in their shanks, and are easily fixed or removed The hand piece is in two parts *only* The cable and hand piece are supported by a rigid steel tube terminating in a spring which relieves the operator almost entirely of their weight and allows of much greater delicacy of touch than would otherwise be possible The motor is started and its speed regulated by means of a foot switch The apparatus ready for use is shown in the figure, and when dismounted it fits into three packages shown at the foot of the figure The case on the left is the accumulator, that on the right contains the motor, stand, turn-table, switch and other fittings, the package on the top carries the legs of the stand and flexible arm The entire apparatus with cases included weighs about 70 pounds For hospital work the motor is wound to suit the voltage of the main current It is mounted on an enamelled steel pedestal fitted with ball bearing castors Burrs drills, a small trephine and Cryer's drill can be used with the motor

THE LANCET.

LONDON: SATURDAY, JUNE 15, 1901.

Medical Union.

FROM its foundation THE LANCET has always attempted to impress upon medical men the importance of united action in professional matters. Medical men are all inspired with the same hopes; we all have the same objects in view; and inasmuch as true medical science is the same wherever taught, we all approach our duties equipped in the same broad way to assist in the prevention of disease and the alleviation of misery. Details of treatment may differ in certain schools—a point in etiology that in one place is regarded as theoretical is accepted in another as proven, but these minor differences of opinion, by leading to comparisons of view, only serve to bring out more clearly the important fact that true medicine has no geographical limits. Therefore it is that medical union ought to be so possible and so useful, and we are certain that it could play a much more important part in our professional life if we realised with clearness what is meant by the words.

A professional union is not a trade union. Two prominent persons have recently accused the medical profession of employing trade union methods towards the public—Mr. CHAMBERLAIN and Lord GRIMTHORPE. Let us deal first with Lord GRIMTHORPE who, although he describes himself in a letter to the *Times* as having once been "a sort of Archbishop," must not be taken seriously. Lord GRIMTHORPE, besides being an ex-quasi-archbishop (he has been Chancellor and Vicar-General of the province of York) is an ecclesiastical lawyer of some note and an amateur architect of more daring than science. His letters to the *Times* have been during his long life frequent and free; they have often been ridiculous, but his recent effusion is silly without containing the saving graces of humour and caustic phrase which we are wont to expect from his pen. Lord GRIMTHORPE considers that the General Medical Council—"a parcel of doctors" as he politely terms it—is guilty of unionist tyranny when it strikes off the roll of the medical profession the name of an unworthy member. He evidently has not the faintest idea of the position which the General Medical Council occupies towards the public and fails to see that its actions in purging the Register are undertaken to protect the public. His attempt to disparage the medical profession in the eyes of the world through the medium of the *Times* offers a sad proof of his advancing years—and no more need be said about it. Mr. CHAMBERLAIN is in a different position. He is one of the most prominent statesmen in the world, his general repute as an able and clear-headed man is universal, while he is a specially experienced judge of trade methods. He also has alluded to the General Medical Council as employing the methods of trade unionism. He is not suffering from senility, and his unfortunate words in the House of Commons in detailed defence of the conduct of Dr. IRVINE were spoken no doubt with conviction. He described the General Medical Council as having placed a stigma upon Dr. IRVINE for the trade union offence of underselling his fellow tradesmen by assisting in certain charitable work. Dr. IRVINE himself, before the General Medical Council on June 8th last, admitted that he quite understood that the question of the scale of fees which was laid down by the Birmingham Consultative Institute had nothing whatever to do with the decision of the Council in finding his professional conduct "as being of a serious character," while he recognised that the only offence alleged against him was that he had been considered to be privy to certain advertisements issued by the Institute. The essential claim of the Birmingham Consultative Institute is that it is not a charity but an institution for self-respecting persons willing to pay proper fees. Mr. CHAMBERLAIN'S misstatement—that Dr. IRVINE was punished by the General Medical Council for taking lower fees than his professional brethren with intent to help a charity—remains uncorrected and doubtless will so remain; and it is possible that this fact has impelled Lord GRIMTHORPE, and other people too old or too stupid to think for themselves, to imagine that the medical profession is banded together in a strict trade union to despoil the public.

Our readers may find this impression among their patients and they would do well to be prepared to explain the difference between a professional union and a trade union. We are not here decrying trade unions. We are not denying that many trade unions have been animated by far nobler sentiments than the desire to extract from the employer of labour the maximum of pay for the minimum of work. If sometimes the tyranny of capital has been replaced by the tyranny of labour the situation is one that usually adjusts itself. But what we desire to point out is that professional union means something more. Medical men are bound together by the nature of their high calling. Professing a science that is one, they attempt to regulate their dealings both with each other and with the public according to a code that is accepted by all, and that has gradually grown up as the intimate and confidential nature of the trust reposed in them became patent to civilised nations. The code has been recognised by the legislature of this country when discretion was granted to the General Medical Council to remove from the Register the names of persons transgressing its laws which, if more or less unwritten, are still so familiar to all medical men. In these well-known circumstances to describe the bond existing between medical men as a simple trade union is to show complete ignorance. For the services which the medical profession renders to the public the medical profession must be paid, and the question has always presented itself to thinking people how far the profession can use the power of union, given by a common basis of knowledge and a common code of ethics, to maintain a proper standard of remuneration. In certain positions it is being gradually recognised that to accept contract work is to come dangerously near infringement of the code. The point of inadequate fees is one thing and one thing only in the question of contract work. Where the employers are laymen the medical man loses his professional independence, and may be placed in a position, as Dr. IRVINE was, where to agree with his lay employers is to transgress the accepted code.

Sanitation and Yellow Fever in Havana.

A DISTINGUISHED American writer has truly said: "By the death-rate all sanitary reforms must be tested. They *will stand the test. Lower the ground water, replace* sewage-soaked wells with an arterial supply from pure sources, let sewers relieve the overburdened ground of the products of waste, empty and disinfect the reeking vaults, cleanse the garbage-strewn alleys, and the death-rate will respond as promptly as the mercury in the barometer tube to the changing weight of the atmosphere." Judged by this test Havana under the American *régime* has been found to be no exception to the rule. The death-rate has been largely decreased, and it is confidently anticipated that when other contemplated sanitary reforms have been introduced the *mortality of the Cuban capital will compare favourably* with that of cities which enjoy a well-established reputation for healthfulness. Major VALÉRY HAVARD, chief surgeon of the Department of Cuba, in a report recently published, comments at length upon the effects of the sanitary reforms already carried out in Havana, but by far the chief interest of his remarks centres in his description of yellow fever in Havana from the point of view of the sanitarian.

The investigations of Major WALTER REED and his colleagues with respect to the etiology of yellow fever, resulting in the theory that it is caused by the bite of a *species* of mosquito, acting, as in the case of malaria, as the intermediary host to man, has thrown doubt on existing beliefs as to the means of transmission of the malady and has consequently also modified prevailing ideas with regard to its prevention. Major HAVARD, it is interesting to note, is a hard-and-fast believer in the views propounded by the American army *savants*, and moreover is extremely sanguine that, acting upon the knowledge of the cause of yellow fever, the task of eradicating both that disease and malaria from Havana will present no insurmountable obstacles. He agrees with Major REED that dirt and filth have nothing whatever to do with the spread of yellow fever except inasmuch as they may attract and feed mosquitoes, and he points out that Major REED and his colleagues conclusively proved by direct experiment that infected linen, bedding, and effects of all kinds are powerless to convey the disease. Major HAVARD cites as a strong argument in support of the truth of this contention that in Havana in 1900 no visible correlation could be seen between dirt and yellow fever, the district which first became strongly infected being one of the cleanest and best constructed, while the most *insanitary wards became infected late in the season and* only to a slight extent. Yellow fever did not follow the poor and unclean or the march of previous infections, but rather the movement of non-immunes. In fact, according to the new theory yellow fever is non-contagious and fomites are inert. With the morbific mosquito out of the way the disease cannot spread. Consequently the problem consists in the extirpation of the culex fasciatus, in the protection of yellow fever patients and all non-immunes with mosquito nets, and in isolation of patients. Disinfection is useless because there are no infectious germs to destroy, but fumigation by formaldehyde gas is recommended in a house in which yellow fever is present and where infected mosquitoes may be lurking. Again, assuming that the infectious germs do not exist except in man and the mosquito, disinfection of baggage is unnecessary and the duty of the quarantine official will be simplified to detaining non-immunes for five days immediately following their last exposure to infection and to fumigating the ship. The chief factors in the propagation of yellow fever being mosquitoes and non-immunes, measures to protect the latter are indispensable with a view to check the spread of the disease. Major HAVARD pertinently remarks that if immigration could be stopped for two or three years, and if during that period all germ-bearing mosquitoes could be destroyed, the city thereafter could be kept as free from infection as Kingston in Jamaica and San Juan in *Porto Rico. But immigration cannot be stopped nor,* probably, can the offending mosquitoes be extirpated with the comparative ease which certain optimistic persons seem to imagine. Much undoubtedly can be accomplished in Havana towards this result by the establishment of an efficient sewerage system, by a thorough drainage of the neighbourhood of the city, and by the protection of non-immunes by every means which lie in the power of the authorities. The inhabitants of this portion of the world, and especially of the Southern States of the Union and South America, as a whole, will watch the efforts to stamp out yellow fever in Cuba with the greatest interest. There can be no doubt that if, as Major REED and his coadjutors assert, the mosquito culex fasciatus is the only agency by which yellow fever is communicated to the human race the task of eradicating the disease will be rendered much easier.

Major HAVARD, at the end of his report, discusses the subject of immunity against yellow fever, and some of his remarks may arouse the attention of those who have made a study of the malady. He says: "Immunity is not enjoyed by all Cubans as popularly believed, but only by those residing in cities, not by those who have lived from infancy in the interior rural districts. In other words, immunity is only enjoyed by the residents of centres where yellow fever is endemic; it is not enough to have lived in a tropical climate, one must have lived in an infected locality. The inference therefore is strong that immunity is acquired only by an attack of the disease; there is no other infectious disease against which immunity is obtained in any other way and there is no reason to believe that yellow fever is an exception to that rule Under the former belief that it was acquired by the absorption of germs through the respiratory passages it was possible to conceive the possibility of a very slow but constant infinitesimal absorption which might in time produce immunity without any apparent fever, but such a conception is no longer tenable if the germs are introduced directly into the blood by the mosquito. Those physicians who assume *a priori* that Cubans, whether they live in the city or country, cannot have yellow fever, decline to recognise it when they find it in natives: they call it *fiebre de borras*, and consider it a special form of malaria which, strangely enough, only occurs in this island." It would be instructive in this connexion to hear the experience of physicians who have treated yellow fever in the British West Indian islands. The entire trend of Major HAVARD'S valuable report, it will be observed, is strongly to confirm the views of Major REED, and is thus, coming from one who has claim to speak with authority, another link in the chain of argument in favour of the new theory of the etiology of yellow fever.

Medical Ethics in France.

OUR readers doubtless noticed in the letter of our Paris correspondent in THE LANCET of April 27th, p. 1242, a statement of certain principles of medical deontology adopted by the Conseil Général des Sociétés d'Arrondissement. It is not inopportune to notice the increased attention which is being given to questions of medical conduct as distinguished from questions of medical practice or science, and the statement referred to is worthy of consideration on account of the time spent upon it and for the purpose of ascertaining whether there is any new principle in it or any new commandment binding on the practitioners of the present day which was not binding on their fathers. The deontological points enumerated by our Paris correspondent have reference mainly to the action of a medical man when he is summoned to see the patient of another practitioner and to the duties of consultants.

The first regulation prescribes that the practitioner called for the first time to a family and finding that he has only been summoned in the absence of the usual medical attendant shall only act as long as the absence of his professional brother lasts. In other words, he is not to take a mean advantage of his brother's absence to appropriate the case to himself. The second regulation deals with cases in which a medical man is called in in the absence of another medical man who has been treating the case and the patient expresses a wish for the future to retain his services. It is ruled that the new practitioner called in may go on attending the case provided that he informs the former medical attendant. In the third regulation the practitioner summoned in an emergency is enjoined only to prescribe such treatment as is immediately necessary, and not to return to the patient's house except in consultation with the usual medical attendant. This is, we think, a little too dogmatic. The case might be one of hæmorrhage, or of strangulated hernia, or of labour, and it might require repeated visits in the absence of the regular adviser. The fourth regulation requires a medical man summoned under the above circumstances to do his best to get the medical man hitherto in charge of the case retained, and in case of failure to inform the previous adviser. In all such cases it is well that the intimation of the patient's wish for a change should be given by the patient or by his friends rather than by the medical practitioner, though there is no reason why he should not privately and in a friendly way intimate the same to the medical brother whom he has superseded. Of course, it is to be assumed that he is a reluctant party to this displacement of a professional brother. If there be anything in professional morals and amenities it is that we are to be neighbourly, to be not only ready, but pleased, to help each other, to put the best construction on each others' work, and to take no advantage of what may be the temporary mood and adverse judgment of a patient with regard to his regular adviser. The man who does not so regard his duty to a medical neighbour has mistaken his calling and is not worthy of it. To hesitate about this, in the absence of any gross fault or carelessness on the part of a professional brother, is to ignore the first principles of medical ethics. Disease does not always respond immediately to the therapeutics of even the most experienced adviser. The new preference of the patient may be a mere whim due to peevishness or to disease. We shall all do well to remember these facts and to apply them in support of our brother practitioners. Any one who succeeds in vindicating a brother practitioner's character has done good service to his profession and gains more than is implied by the petty temporary acquisition of a new patient. If he fails and is obliged reluctantly to accept the case as contemplated in the second regulation he has at least done his duty, and has given proof to the laity that much as the true medical man appreciates a new patient he appreciates still more the obligations of his profession and the spirit of neighbourliness and mutual help in which they originate.

We must not omit to notice the last two regulations. The seventh regulation requires a practitioner to be generous in accepting as a consultant the practitioner proposed by the patient or by his family, whatever be his age or his status, "provided that his personal and professional honour is above suspicion." We highly approve of the wisdom of this suggestion. It is not for the practitioner in attendance to be critical as to the superiority of the consultant desired by the patient. He may give his general views on the matter, but he will act magnanimously if he seeks to satisfy and to please the patient. Even if the consultant is much younger than himself and of shorter experience he will do well to meet him with readiness. Nothing is more honourable to age than its appreciation of younger men, and perhaps the best consultations are those which involve such diverse advantages. We are not quite so sure about the eighth regulation, which tells us that the consulting-room is neutral ground where a medical man may give advice to anyone coming to consult him "without any regard to the medical man who usually looks after" him. Surely this is a doubtful doctrine that must be revised. The right of the patient to have whatever opinion he may prefer has been very properly vindicated in these regulations, and that may include the right to have the opinion of a consultant independently of that of his usual adviser. But "without any regard to the medical man who usually looks after him" is a very strong way of emancipating consulting practice from all obligations to general practitioners, and one of very doubtful advantage, we feel sure, to the patient. It is a new piece of medical ethics which will find no support in old authorities. We regard it with entire suspicion and disapproval, as tending to prevent that mutual and respectful coöperation in the diagnosis and treatment of difficult cases which is so desirable, and, we are glad to add, so usual, on the part of the consultant and the general practitioner.

Annotations.

"Ne quid nimis."

THE CARNEGIE TRUST.

THE particulars of the trust-deed and constitution whereby Mr. Carnegie proposes to secure the benefits of his munificence to the Universities of Scotland and their students have now been made public. The scheme as thus formulated has two features which rivet attention and which commend it to us at least as strongly as does the list of carefully selected men of mark who are to be responsible for safeguarding and administering the revenues placed at their disposal. In the first place the executive committee, consisting of nine of the trustees, is to have a free hand—that is to say, it is to deal with the income of the trust at its own discretion, expending its moneys as it may think best so long as it keeps in view the main objects of the founder's munificence. The circumstances and requirements of educational life undergo constant changes. Developments may occur at any time in the near or distant future which the most far-seeing and studious observer of the present day could not by any means in his power forecast, so that to have tied the hands of the trustees of Mr. Carnegie's millions by accurately prescribing their duties to-day might have fatally interfered with the usefulness of their successors, who, as matters stand, will be able to adapt their measures to the educational needs of future generations without hindrance and without appeal to courts of law or other supervising tribunals. It would be easy to point to instances at our older public schools or in our universities of the gift of the donor who has tried strictly to limit its application, with the result that it has for long benefited no person or object in the manner which the giver intended, and that in the end the fund has attracted the attention of the Charity Commissioners who have had to devise or to sanction new objects of expenditure entirely remote from anything that the founder knew of or desired. The objects to which Mr. Carnegie's trust are to be devoted are divided into two general classes, so that one-half of the net annual income is to be applied towards the improvement and expansion of the Universities of Scotland in the faculties of science and medicine, also for improving and extending the opportunities for scientific study and research and for increasing the facilities for acquiring a knowledge of history, economics, English literature, and modern languages, and such other subjects cognate to a technical or commercial education as can be brought within the scope of the university curriculum, by the erection of buildings, laboratories, class rooms, museums or libraries, the providing of efficient apparatus, books, and equipment, the institution and endowment of professorships and lectureships, and by similar measures which we need not give in detail; while the other half of the income, or such part of it as may in each year be found requisite, is to be used for the purpose of defraying the educational fees of students of Scottish birth, within limitations given, a disposition for which the early announcement of Mr. Carnegie's intentions had prepared us. The prominence given above to science and medicine, and to the providing of opportunities for scientific and medical study shows how closely Mr. Carnegie and those who may have advised him have studied the subject which they had to deal with and appreciated the relative difficulties which beset education and those who desire to make it thorough and effective. We may fairly say that in respect of costliness of apparatus the education of the medical practitioner stands almost alone. In the preparation for other professions there are charges for lectures and tuition, and fees are paid for the privilege of observing the work of others. In the case of other professions as well as of medicine, books, sometimes expensive books, form part of the necessary equipment of the student, but the costly instruments, the microscopes, the subjects of dissection and experiment, the whole apparatus of chemical research, can hardly be said to have a parallel in the early career of the would-be clergyman or lawyer, of the business man, or the soldier. In the case of these others, moreover, the intelligence of the student may sometimes enable him to dispense with aids which are necessary to his colleagues, and thus to educate himself at less expense. But the student of science differs from these. The further he goes the further his ambition calls him, and the greater his intelligence the wider, and in consequence the more costly, becomes the field of his researches. The gift which we are discussing will mark an epoch in the educational history of Scotland, a country in which education has ever been held in high honour and esteem, but we have little doubt that it will be those who in future years are preparing themselves for the practice of the medical profession and for other scientific pursuits who will have best reason to recall with gratitude the name of Mr. Carnegie. In America, where that gentleman has amassed his wealth, the endowment of educational centres on a colossal scale and other large-minded schemes for the public welfare have far more frequently than with us afforded the means by which successful men of business have sought to commemorate their fame and to show their gratitude to the Providence which has favoured them. If the example of Mr. Carnegie is followed in these islands he may have done more than benefit the Universities of Scotland; he may have originated a movement with far-reaching results, and have instituted a practice by which our great universities and many other institutions of national importance may be glad to profit. The names which they commemorate on the occasions prescribed for the praise of departed benefactors usually belong to periods of more or less remote antiquity, certainly to dates when wealth was less common and less vast than it is now.

A DAY IN THE COUNTRY.

THIS is the time of year when appeals are made to the public charity for money with which to give London children "a day in the country." The question is raised whether such a day does not bring harm rather than good, crowded as it is with the excitement and the strain of compressing as much experience as possible into the sixteen or so available hours. The Rev. S. A. Barnett, writing from Toynbee Hall on this subject, believes that in these children's treats is laid the foundation of a system of "days off" for workmen which is anything but beneficial to those for whom such holidays are the only ones at present available. If there were fewer single holidays and the workman could have every year a fortnight's consecutive freedom from work and from town he would, in Mr. Barnett's opinion, lose the idea that excitement is the only possible form of pleasure. Whether a difference in the arrangement of his holidays could effect such a difference in the bent of the workman's mind is open to doubt, but all must agree that the day's holiday, whether for men or for children, might be better spent than in the crowded trains, the rush, the scrambling feeding, and the bustling excitement of the "excursion" or the "school-treat" with which we are familiar. In the case of children it is incumbent upon the adults who conduct, as well as upon those who generally supply the funds for, the outing to see that the child's day in the country does not mean that natural sleep is curtailed by several hours, that the child is not herded into a carriage over-filled, is not crammed with food, hustled through games, re-packed into the carriage and brought back to London without having a chance of realising the quiet spirit, breathing the pure air, and noticing the gentle sweetness of the country side. It is not necessary for the holiday to be a long one to allow a London child to benefit by the country and to gain an impression which will dwell brightly in his memory for long days. Let him only be taken not too far a journey in not too great numbers and let him wander at his will in the quiet fields without being hurried into games or regulated sports. Even a few such free hours are full of physical and mental good for the child or the man who lives in a crowded city.

SIR WALTER BESANT.

THE late Sir Walter Besant was a philanthropist in the most literal sense of the word. He loved his fellow-men and spared no pains in their behalf. Of the most genial temperament and delighting in the happiness of others, the grey, depressing lives of the poor of London moved him to deep pity. A tireless worker, his heart bled for the seamstress whose day of labour was longer even than his own. A successful man from the opening of his literary career, his sympathy went out to all of his craft whose labours met with no return. His vision of a People's Palace to bring light into gloomy Whitechapel became a reality; his scheme for organising men and women of letters into a coherent body for the maintenance of their common rights resulted in that useful corporation, the Society of Authors. Of Sir Walter Besant as a scholar, a humourist, a novelist, and an antiquary much might be written and much will be written. But from a medical point of view it will suffice to say that the healthy recreation which his sane and beautiful stories brought to a vast circle of readers had its physical value, while his vivid and picturesque pourtrayal of eighteenth-century manners served to make us understand the processes of social evolution in a way that no dry-as-dust treatises could aspire to do. The death of such a man, devoted to well-doing, whose sanguine energy insured a practical effect for the dreams of his well-dowered brain, is a loss to the world, and we desire to pay tribute to our sense of this loss.

PUNCTURE OF THE KIDNEY FOR NEPHRITIS.

THE surgeon is ever invading the province of the physician, and so accustomed have we become to this that we hear without surprise of some new surgical method of treatment for a disease always hitherto assigned to the physician, but of all morbid conditions inflammation of such an organ as the kidney might have been thought the least likely to be subjected to the surgeon's knife. A few years ago Mr. Reginald Harrison, in his presidential address to the Medical Society of London, drew attention to the numerous cases which have been recorded in which a kidney has been cut down upon in expectation of some gross lesion being found and nothing of any importance has been discovered, yet decided improvement in the symptoms has followed the operation. Mr. Harrison suggested that the improvement was due to the relief of tension. This was a novel idea, but the results of the ordinary medicinal treatment of acute inflammations of the kidney are so unsatisfactory that we can only welcome any treatment which seems to offer a reasonable prospect of success. The subject is to be discussed at the Cheltenham meeting of the British Medical Association, the introductory paper being read by Mr. Harrison. We may hope to have the matter fully elucidated at that meeting. When we consider analogous cases we see how much damage may be done to delicate organs by mere increase of tension, and the damage is in a large degree proportionate to the teneseness of the capsule. In the eye a very slight increase of internal pressure suffices to damage irreparably its essential structure, and the name "renal glaucoma" has not inaptly been suggested for the truly analogous condition in the kidney. How far the operation of incision of the kidney can prevent or relieve the effects of congestion time alone can show, but the subject deserves the careful attention of all surgeons.

CHARING CROSS HOSPITAL: THE CHÈRE REINE LODGE OF FREEMASONS.

THE Chère Reine Lodge, No. 2853, was consecrated on June 7th at the Hotel Cecil, Strand, London, W.C., by V. W. Bro. Edward Letchworth, F.S.A., Grand Secretary, assisted by the following Grand Officers: R. W. Bro. Robert Grey, P.G.W., as S.W.; V. W. Bro. Edward Terry, P.G.T., as J.W.; V. W. Bro. Rev. Sir Borradaile Savory, G. Chaplain as Chaplain; W. Bro. Fitzroy Tower, as D.C.; and W. Bro. Woodhouse Braine, F.R.C.S., S.G.D., as I.G. The Chère Reine Lodge is the sixth lodge connected with medicine to be established in the metropolis and Charing Cross Hospital is the fifth of the London hospitals to associate itself with Freemasonry, following the good lead set by St. Bartholomew's, St. Mary's, the West London, and the Middlesex Hospitals. The officers appointed were W. Bro. Rev. A. W. Oxford, M.D. Oxon., P.G.D., Worshipful Master; Bro. John Abercrombie, M.D. Cantab., F.R.C.P., Senior Warden; Bro. Amand Routh, M.D. Lond., F.R.C.P., Junior Warden; W. Bro. J. Astley Bloxam, F.R.C.S. Eng., I.P.M.; W. Bro. C. E. Wright, Chaplain; R. W. Bro. Robert Grey, P.G.W., treasurer; Bro. C. Carter Braine, F.R.C.S., secretary; Bro. Frederick Wallis, M.B. Cantab., F.R.C.S. Eng., S.D.; Bro. Victor Corbould, M.D. Brux., J.D.; Bro. J. W. Eyre, M.D. Durh., I.G.; W. Bro. Arthur E. Reade, Organist; and Bro. P. L. Daniel, F.R.C.S. Eng., and Bro. J. Humphreys, L.D.S. Eng., Stewards. After the ceremony of consecration and the conclusion of business the Founders entertained their numerous guests at a banquet. The usual loyal toasts having been duly honoured the W. Master proposed "The Consecrating Officers" which was suitably acknowledged by the Grand Secretary. "The Worshipful Master" was proposed by W. Bro. Astley Bloxam, and W. Bro. Oxford in replying modestly regretted that he was filling a post which ought to have been occupied by one of the staff of the hospital had circumstances permitted. He then proposed the toast of the "Visitors," which was responded to by W. Bro. Surgeon Lieutenant-Colonel Kiallmark, W.M. of the University of London Lodge, W. Bro. L. Bidwell, F.R.C.S., W.M. of the Cavendish Lodge (West London Hospital), and W. Bro. A. E. Sansom, M.D. Lond., F.R.C.P., who is W.M. designate of the Lodge shortly to be founded in connexion with the London Hospital. "The Officers of the Lodge" was acknowledged by Bro. Abercrombie, Bro. Routh, and Bro. Carter Braine, the last-named remarking that although it might be imagined that the name "Chère Reine" had been adopted in connexion with the name of the hospital this was not actually so. It was rather selected because one of the crosses erected by King Edward I. to commemorate the route of Queen Eleanor's funeral procession was at the village of Charing, near to Westminster Abbey, and because it was thought that the recent death of Her Majesty Queen Victoria, who was Patroness of Charing-cross Hospital, would make "Chère Reine" a doubly appropriate designation for their lodge. We have no doubt that the experienced and able guidance of its first Master will prove of great assistance to the Chère Reine Lodge in starting on a career which there can be no doubt will be one of usefulness and success. At all events, it will have the hearty good wishes of every medical Freemason.

THE CORONERSHIP OF THE CITY OF LONDON.

AT a meeting of the Officers and Clerks Committee of the Corporation the three following gentlemen were placed upon the selected list of candidates for the City Coronership—Dr. *Major Greenwood*, Dr. *H. R. Oswald*, and *Dr. F. J. Waldo*. All three of these gentlemen are barristers as well as members of the medical profession and we feel that we cannot do otherwise than congratulate the Corporation of the City of London on their choice. We have placed the names alphabetically and, so far as we are concerned, shall be pleased to see any one of the three candidates successful. Although Dr. Oswald is the only one who has already had experience in the actual office of coroner, both Dr. Greenwood and Dr. Waldo have, we believe, assisted Dr. Danford Thomas in a large number of inquests. The final election will take place at a meeting of the Court of Common Council on Thursday, June 20th.

THE DEVON AND CORNWALL ASSOCIATION FOR THE PREVENTION OF CONSUMPTION AND OTHER FORMS OF TUBERCULOSIS.

THIS society appears to be doing good work in the West of England. It is well that everyone should have definite knowledge as to the cause of preventable disease and the general spread of information on this subject is not the least valuable part of the work of the society. The Earl of Mount Edgcumbe who presided over the annual meeting which was lately held at Plymouth gave in his opening speech a *résumé* of some of the methods by which pulmonary tuberculosis is spread, and this information generally disseminated by means of the western morning papers is likely to be productive of unmixed good. According to the annual report given by the Executive and Sanatorium Committee of the society the total number of deaths from pulmonary tuberculosis which occurred in Devon and Cornwall amounted during last year to 1000. It was estimated that 3000 persons were suffering from the disease, but it is not easy to imagine how reliable statistics on this matter could be obtained under existing circumstances. The committee advise that a sanitary staff shall be appointed to assist the voluntary efforts for the prevention of tuberculosis. It was also suggested that a bacteriological laboratory for the early diagnosis of the disease and a home for advanced cases were wanted. The chief practical work of the committee has been directed to making preliminary observations as to the provision of a sanatorium and it seems that at present there is not entire agreement as to the best method to be adopted, there being a difference of opinion as to whether one sanatorium should be built or whether each of three districts should have a separate sanatorium. This is a matter on which local considerations must of course prevail, for those who give the necessary money will naturally feel that they have a right to decide how it can be spent to the best advantage. The Earl of Mount Edgcumbe stated that the County Council of Cornwall had promised to subscribe to the association to the extent of £50 per annum for two years, but a question has arisen as to the legality of this grant. During the course of the debate which was held on the annual report which was presented to the meeting some interesting remarks were made by Dr. Lionel A. Weatherly, chairman of the Executive Committee of a similar association which has been formed for the counties of Gloucester, Somersetshire, and Wiltshire. Dr. Weatherly stated that his association had decided to build a sanatorium for the accommodation of 60 patients and he was strongly of opinion that the constant supervision of a medical man was necessary to ensure the best results to the patients who were under treatment. The beds were to be allotted to the three counties named and to the city of Bristol, the arrangement being that each of these districts should have a right to send 15 patients. The cost of maintenance of the institution was to be provided in part by a system of insurance under which clubs would contribute a weekly payment according to their numbers. The estimated cost of the sanatorium was £65 per bed per annum and it was expected that the chief trouble would not be in getting the necessary money but that it would arise rather from the excess of patients from whom the selection would have to be made. In the case of poor patients Dr. Weatherly said that they would not ask their friends to contribute more than 10*s.* per week. Boards of guardians, he thought, ought not to be allowed to subscribe for a bed, firstly on the ground that it was undesirable to "mix up different classes of poor patients," and secondly, because guardians could treat their patients "in the workhouse grounds." There are, it is to be feared, in Devon and Cornwall many poor patients who could not afford a payment of 10*s.* per week, a sum which in some places is the exact amount of the weekly wages of a labourer. After a long discussion it was proposed that separate committees should be formed in Exeter, Plymouth, and Truro, with a view to take measures to establish, and eventually to control and to manage, a separate sanatorium for each of the three districts. The mayor of each of the towns named was to be asked to convene a public meeting for the purpose of appointing such committee, and each committee was to act independently. As we have stated, the meeting differed as to whether there should be only one sanatorium or three separate institutions, and it was finally resolved that this question should remain undecided. Local and financial as well as sentimental reasons will doubtless affect the decision ultimately made as to the place or places selected and the solution of this question can be confidently left to those who are acquainted with all the circumstances.

THE CHOICE OF CLIMATE IN PULMONARY TUBERCULOSIS.

ONE of the most frequent questions that a physician has to answer is as to the climate that should be selected for the residence, temporary or permanent, of a patient suffering from pulmonary tuberculosis. The views of physicians have changed considerably with the lapse of years as to the mode of life which should be adopted by patients afflicted with this disease. At one time warm climates were recommended, at another cold, dry regions were chosen, and within the last few years the "open-air" treatment has led to further modifications in their views, and many authorities contend that numerous situations in this country are quite suitable as sites for sanatoria in which this form of treatment may be carried out. In a paper by Dr. W Gordon, entitled "The Practical Choice of Climate in Phthisis," which will be found at p. 1677 of our present issue, the position of climate in its relation to tuberculosis is carefully considered. May we here again express our opinion that the term "pulmonary tuberculosis" is preferable to that of "phthisis" as expressing in exact terminology the nature and site of the disease? Dr. Gordon briefly reviews some points in the controversy which he aptly terms "sanatorium *versus* climate," and argues, quite soundly, that it would be an act of folly to discard the assistance which a climate of proved value can afford to rational treatment, and quotes statistics demonstrating the results that have been obtained in the different "stages" of the disease in various climates. We believe that many fallacies have probably crept into these figures owing to the want of unanimity in deciding as to the meaning of the "first, second, and third stages" respectively of pulmonary tuberculosis; but with that point we are not at present concerned. The remarks to which we would particularly draw attention are those on "home climates." These are eminently worthy of perusal. Dr. Gordon says that sites chosen for sanatoria should satisfy those conditions which experience has shown to be important for success. He then briefly states such conditions: a dry soil, pure air, abundant sunshine, the absence of wind (especially "wet wind"), the absence of dust, the absence of fog, and the avoidance of the immediate sea-front, by which he does not mean, however, an avoidance of the seashore. These suggestions will recommend themselves to all physicians who have had experience in this form of treatment. Dr. Gordon also urges that those areas should also be selected where there is a naturally low mortality from pulmonary tuberculosis. There is another point that might have been referred to—namely, that the "open-air" treatment is at present mainly open to the wealthy. We trust, however, that the time is not far distant when suitable sanatoria may be built for that class of patients who are unable to afford the fees now requisite for the support of the existing sanatoria. Efforts are already being made in this direction, the Hospital for Consumption, Brompton, being one of the foremost in preparing to establish a branch in the country for the treatment of early cases of the disease.

THE DETECTION AND DETERMINATION OF ARSENIC.

THE recent beer-poisoning epidemic has led to an enormous number of contributions on the chemistry of arsenic, on its detection, and on its determination. And we are by no means sure that the issue has been cleared. Some chemists are in favour of one method and some in favour of another, fallacies are pointed out in methods previously held to be exact, and discarded methods have come to the front again, being, as it is asserted, made more accurate by some modification in detail. Again, even assuming that we have a certain and trustworthy method for the detection of arsenic we yet await a consensus of opinion as to the method which will give accurate quantitative results in cases where the arsenic present is in infinitesimal amount. All contributions towards the elucidation of this aspect of the problem must be welcomed, for the issue is of the utmost importance. We are glad, therefore, to find that the council of the Society of Chemical Industry have thought it desirable to republish in pamphlet form the papers, discussions, and abstracts which have recently appeared on this subject in the columns of the society's journal. The reprint is most instructive and should be of the greatest value to those possessing a practical interest in the subject. It furnishes at once a guide to the best methods for detecting and determining arsenic and the other poisonous elements associated with it. It contains also abstracts of analytical methods from various scientific publications. The publication, too, of the scientific discussion on the subject is most valuable. Some idea of the contents of the reprint may be gained from the following synopsis:—The Determination of Arsenic and Antimony in Cupreous Materials; the Discussion on the Occurrence and Detection of Arsenic in Manufactured Products at a Meeting of the London Section of the Society; the Effect on the Marsh Test of some Commercial Products containing Selenium and Tellurium; Arsenic in Coal and Coke; the Detection of Arsenic in Beers, Brewing Materials, and Food; the Discussion (at the Manchester Section) on the Need of a Standard Test for Arsenic; the Discussion on the Presence of Arsenic in Beer (Nottingham Section); the Presence of Arsenic in Beer (New York Section); the Determination of Minute Quantities of Arsenic in Coke (Nottingham Section); and Arsenical Beer and Malt (Yorkshire Section). An interesting addition to the literature of the subject is the original description of Marsh's test in the author's own words, together with the modifications proposed by Berzelius, Fresenius and von Babo, and also by Otto. From a perusal of this reprint we do not seem to be nearer to the solution of the problem as to whether arsenic *per se* is responsible for the whole of the trouble. The interesting facts, however, have been brought out that a penicillium can extract arsenic and that a sample of Bostock's sugar has been found to develop a greenish mould and to give off an odour of garlic with just a suggestion of phosphorus. A word of thanks is due to the council for publishing in separate and convenient form this interesting contribution on the detection and determination of arsenic. Copies may be obtained from Messrs. Eyre and Spottiswoode, East Harding-street, E.C.

HYGIENE IN GERMAN SCHOOLS.

IT is generally admitted that continental schools, although their educational reputation may be well-deserved, nevertheless leave much to be desired from a hygienic point of view. We are therefore glad to observe that in Germany a movement is in progress for the improvement of the hygienic condition of schools throughout the empire. The Allgemeiner Deutscher Verein für Schulgesundheitspflege (General German Association for the Promotion of Hygiene in Schools) has been in existence for rather more than a year and held its second annual meeting at Wiesbaden on May 31st, when the following interesting subjects, among many others, were discussed: (1) the new Prussian school reform in relation to school hygiene; (2) the general conditions of school hygiene, with reference to Wiesbaden in particular; and (3) school hygiene in relation to infectious diseases, especially tuberculosis. That this association meets a want is now recognised, for the *Berliner Tageblatt* of May 25th announces that an association of very similar character and aims has quite recently been founded in Berlin.

GWYNNE *v.* GREVILLE.

AN interesting case has recently occupied the attention of the Lord Chief Justice and a special jury in the Court of King's Bench. The action was brought by Mrs. Agnes Gwynne and her husband against the Medical Electro-Thermic Generator Company, Limited, and Mr. A. E. Greville. The latter gentleman is a solicitor and the managing director of the defendant company, being also the inventor and patentee of the bath. Put shortly, it is an apparatus whereby dry highly-heated air can be applied to a limb or other parts of the body. Mrs. Gwynne had two baths which were applied to her legs without any harm arising. During a third bath, which was applied to other parts of the body, Mrs. Gwynne was severely burned owing to the bath not having been properly packed. Evidence was given that enough lint was sent to pack the bath properly, but evidence was also given to the effect that no lint was sent. Whichever statement was correct it is obvious that the lint was not used. The bath was applied by a nurse whose sole experience of such baths was that she had been presen[illegible] the giving of the first two baths. It is fair, however, [illegible] mention that Mr. and Mrs. Gwynne objected to pay[illegible] the fee for the experienced nurse sent out by [illegible] company, and preferred their own. At the third bath Mr. Greville, jun., was present, but he did not see for himself whether or not the bath was properly arranged, but merely asked Mrs. Gwynne if she was, properly packed. She replied in the affirmative and he then turned on the current. In the end the jury found for the plaintiffs with one farthing damages. The personal liability of Mr. Greville was not considered but only that of the company. We are sorry for Mrs. Gwynne, but the case is only one more example of the foolishness of making use of powerful agents without medical supervision. The lesson which it teaches is, to our minds, that medical men should not only be content with advising the application of such remedies, but should supervise their application. The company, too, would be well advised if they were to refuse to apply their apparatus without the supervision of the patient's medical man, or at any rate of some one delegated by him.

DINNER TO SURGEON-GENERAL JAMESON, C.B.

WE are glad to be able to announce that at a recent meeting it was determined that a complimentary dinner should be given to Surgeon-General Jameson, late Director-General of the Army Medical Service. On another page we print a list of names of distinguished and representative members of the profession who are interesting themselves in the movement. The list already includes the names of the President of the General Medical Council, the Presidents of all the various Royal Colleges of Physicians and of Surgeons in the United Kingdom, many well-known members of the staffs of English, Scotch, and Irish hospitals, and most of the gentlemen who served as consulting surgeons to the forces in the war in South Africa. Such a compliment as is implied by this dinner cannot fail to be gratifying to Surgeon-General Jameson, testifying as it does to the high appreciation in which he is held by the whole body of the profession to which he belongs. We trust—indeed, we feel sure—that the gathering will prove a brilliant success.

THE REDUCTION OF TEMPERATURE IN FEVER BY "EVAPORATION BATHS."

IN the *Journal of the American Medical Association* of May 18th Dr. Francis H. Williams describes a method of reducing temperature in fever by "evaporation baths," which he claims are much more comfortable than the ordinary cold bath. The method is similar to that which has been used for many centuries in hot countries to cool drinking-water. To ascertain its efficiency Dr. Williams took a large bottle holding about a gallon of water at a temperature of 104° F. and wrapped it in surgical gauze which he sprinkled with water at the temperature of the room, at the same time continuously fanning the bottle with an electrical fan. He found that the water in the bottle could be cooled in half an hour about 24°F. below its initial temperature of 104° F., the temperature of the air in the room being 70° F. He also varied the number of layers of gauze covering the bottle and found that one or two gave better results than a greater number. He also compared electrical fanning with hand fanning and found that the temperature was reduced much more by the former. In private practice hand fanning is quite feasible, in a hospital the electrical method is better. To compare the effects of ice water with warm water, Dr. Williams placed two gauze-covered bottles in the same current of air and kept one wet with water at 100° F. and the other with ice water. At the end of half an hour the difference in temperature of the bottles was only 1° F. Hence the slight increase in cooling obtained by sprinkling the patient with cold instead of warm water does not counterbalance the discomfort of the former. Moreover, the warm water has the advantage of attracting the blood to the surface of the body. The method of giving the bath is as follows. A rubber cloth or woollen blanket is put under the patient. Strips of coarse gauze are then placed on him in a single layer sufficient to cover three-fourths of the legs, arms, and trunk. The gauze is sprinkled with water at a temperature of 110° F. and is kept wet, and the patient is fanned. In the first bath it is well to use a pint of water and in subsequent baths to be guided by the effect of the previous one. The time required for evaporation varies with the amount of moistening in the air. It is better to be guided by the quantity of water evaporated than by the time taken. The doors of the room should be kept open and the windows also in warm weather as long as the temperature is 102 °F. or more. The patient should have as little clothing as possible, only a sheet, and in private practice he may be without covering. The average reduction in temperature obtained by 22 baths given in July to patients suffering from typhoid fever was 2·6°; the time required for each bath varied from 15 minutes to half an hour and the amount of water used was about a quart. The temperature was taken in the mouth and the maximum reduction was sometimes not obtained for one or even two hours after the bath. Once the temperature fell 4° and once 5°. In giving these baths the possibility of weak patients collapsing should be borne in mind. Dr. Williams has used this method with great success in typhoid fever and pneumonia. The delirium became less and the patient slept better. The following case is an example. A strong man had typhoid fever with a temperature frequently above 103° F. during three weeks. He was given the baths twice or thrice a day, or whenever the temperature reached 103°. Each bath lasted about half an hour and about a quart of water was used. The average reduction of temperature in ten baths was 2·2°.

"TO KILL THE INSECTS."

AMONGST many popular fallacies none, perhaps, is more pernicious or more tenaciously held than that the addition of spirits to water "kills the insects in it." While some doubt is entertained as to the character of plain water, yet all risk of swallowing germs is supposed to be avoided by drinking the water plus an addition of whisky or other spirit. In other words, the whisky is assumed to sterilise the water and to make it germ-free. It does nothing of the kind. Some organisms, and certainly their spores, will live in alcohol of nearly 75 per cent. strength, which is considerably over the strength of most spirits consumed. The common alcoholic strength of whisky is about 40 per cent., of brandy 42 per cent., and of rum not usually more than 60 per cent. Even supposing, therefore, that these spirits are consumed "neat" no security from germ life would necessarily be gained. It is quite certain that microbes can live and thrive in the ordinary mixed drink of whisky-and-water, the average amount of alcohol in a tumblerful of whisky-and-water, in the proportion usually adopted, being not more than 10 or 11 per cent. Bacteriological investigations have shown that most germs are not affected by a liquid containing 22 per cent. of alcohol, whilst their corresponding spores are unharmed in 83 per cent. alcohol. Alcoholic drinks therefore cannot be regarded as effectual destroyers of microbe life, and, further, bacteria after a time seem to get accustomed to alcohol and to become proof against any antiseptic action that it originally may have possessed. But whisky is often mixed with mineral or aerated water, and in this case there is another factor to deal with—namely, carbonic acid gas. There is no doubt that carbonic acid gas dissolved under pressure in water has a marked antiseptic action, for aerated waters have been found in many cases to be sterile. It would appear, however, that the germicidal action of the gas is slow, and thus natural mineral waters in which the gas has been in very long contact with the water are more likely to be germ-free than freshly and artificially impregnated waters. It is probable that it is not carbonic acid gas that is *per se* destructive to germs, but the definite compound which it forms with the water—namely, true carbonic acid. It is well known that mineral acids are germicides, and in many respects water which is highly charged with carbonic acid gas behaves as a mineral acid. The highly resistant anthrax bacillus and its spore are not, however, affected by carbonic acid, but according to the results of several scientific inquiries the gas in mineral waters is certainly destructive to the pathogenic bacteria—as, for example, those of typhoid fever and cholera. It would be rash, however, to place confidence in either alcohol or carbonic acid as safeguards against pathogenic organisms or to regard whisky-and-water as safer than plain water, while the addition of soda-water is not necessarily to be relied upon to remove bacterial taint.

THE UNIVERSITY OF LONDON.

THE organisation of the University is now practically completed so far as its senate, academical council, faculties, and members of convocation are concerned, and these bodies are engaged in drawing up new regulations for the future conduct of the University. The medical schools have been asked to consider if any, and which, of the preliminary scientific medical studies can be concentrated at one or more centres, but the difficulties in regard to any effective concentration are very obvious. Technical schools for engineering in West Ham and for tanning in Bermondsey have been strongly urged by a correspondent in the *Times*, but assuredly the senate will first deal with university training and scientific research, leaving technical schools in so-called "applied science" to be founded afterwards. The University of London must be truly scientific in its training and methods.

THE LIVERPOOL SCHOOL OF TROPICAL MEDICINE.

THAT energetic society the Liverpool School of Tropical Medicine is sending out another expedition to Sierra Leone. At present the members of the expedition are Major Ronald Ross, I.M.S (retired), F.R.S., and Dr. Logan Taylor, and they will endeavour to ascertain whether mosquitoes of all kinds can be largely reduced in numbers by a year's effort at a reasonable price. A Glasgow donor has given a sum of £1000, and passages, together with plant for mosquito killing, such as oil, cement, chlorine compounds, and insect fumigators, have been provided by Mr. A. L. Jones, Mr. John Holt, Mr. Max Muspratt, Messrs. Hignett Brothers, and others. There are funds enough in hand to maintain, if necessary, 30 native assistants, and measures have been devised for accurately gauging the decrease in the number of mosquitoes. The expedition sails by the *Axim* to-day (Saturday). On June 6th a dinner was given by Mr. A. L. Jones, the president of the school, when a number of guests met at the Adelphi Hotel, Liverpool, to wish Major Ross and his companion good-bye. Mr. Jones presided and among the guests were the Lord Mayor, the Lord Bishop of Liverpool, Professor Rubert Boyce, Surgeon-General Harvey, Dr. H. E. Annett, Dr. Fielding Ould, the United States Consul, the French Consul, the German Consul, and many others. After the royal toasts had been given the chairman proposed "The Expedition," coupling with it the names of Major Ross and of Mr. Swanzy. He pointed out how much the Liverpool School of Tropical Medicine had already done and paid a warm tribute to the work of Professor Boyce. The expedition that was about to start was one of the most important that had ever left these shores and any discoveries which might be made would be used for the benefit of the whole world. We must congratulate Liverpool upon the energy and munificence of her citizens. Such good work has already been done in the matter of malaria that we may hope at no very distant date to see that West Africa has lost the unenviable title of "The White Man's Grave." All honour to those who spend their money and their time and risk their lives in the attempt to bring about so desirable a result.

MR. GEORGE HERRING'S MUNIFICENCE.

AGAIN we have to chronicle the princely generosity of Mr. George Herring to the Metropolitan Hospital Sunday Fund. The Lord Mayor in his letter which we publish to-day announces that Mr. Herring for the third consecutive year has contributed a donation of £10,000 to the Fund. What such a sum as £10,000 means when devoted to the needs of the suffering poor, what it represents in succour to them in their sorest need, can hardly be imagined. And the value of the gift is enhanced in our eyes by the method of its giving. Simply and without condition Mr. Herring hands this great sum to the Metropolitan Hospital Sunday Fund, feeling certain that in this way it will be distributed so as to secure for the objects of his charity the maximum good. This is exactly the view that we want the public to take. In the Metropolitan Hospital Sunday Fund and the Prince of Wales's Hospital Fund for London we have two institutions which by minute and careful investigations arrive at an intimate knowledge of the work done by all the London hospitals. They know the proportionate needs and deserts of all the institutions, so that money distributed through their agency is sure to reach the place where it will do the most good.

PLAGUE IN CAPE COLONY.

A TELEGRAM received at the Colonial Office on June 6th gives the following statistics of plague at Cape Town for the week ending June 1st:—Fresh cases: Europeans, 2; coloured persons, 5; Malays, 0; Indian, 1; Chinese, 0; natives, 3; total, 11. Corpses found: Europeans, 2; coloured persons, 3; Malays, 0; Indian, 1; Chinese, 0; natives, 1; total, 7. Deaths (including corpses found): Europeans, 2; coloured persons, 4; Malays, 0; Indians, 2; Chinese, 0; natives, 2; total, 10. The total cases up to June 1st are as follows: Europeans, 173; coloured persons, 309; Malays, 48; Indians, 11; Chinese, 1; natives, 142; total, 684. The total deaths have been: Europeans, 57; coloured persons, 159; Malays, 35; Indians, 8; Chinese, 0; natives, 59; total, 318. The area of infection remains the same. Seven cases have so far occurred at Port Elizabeth, including 1 suspect.

THE BRITISH CONGRESS ON TUBERCULOSIS.

ALTHOUGH the details of some of the "functions" are not yet completed, a number of arrangements have already been made. The principal railway companies in Great Britain have consented to issue return tickets at a single fare and a quarter, minimum 1*s*. Such tickets will be available from the day before to the day after the Congress, Sunday being considered a *dies non*. On the evening of Monday, July 22nd, the opening day of the Congress, a reception will be held by the Organising Committee in the Queen's Hall, when the band of the Royal Engineers will be in attendance. On Tuesday, the 23rd, Professor Koch will address a public meeting in St. James's Hall, and in the evening a reception will be held by the Lord Mayor in the Mansion House. On Wednesday afternoon, the 24th, Professor Brouardel of Paris will address a public meeting in St. James's Hall at 3 o'clock and from 4.30 to 7 P.M. the Ladies' Reception Committee will give a garden party in the Royal Botanic Society's

Gardens. On Thursday afternoon, the 25th, the Earl and Countess of Derby will give a reception, and on Friday afternoon Sir J. Whittaker Ellis will entertain members and their friends at a river party at Richmond. On Saturday, the 27th, excursions will be arranged to sanatoria and other places of interest and in the afternoon the Duke of Northumberland will give a garden party at Syon House. The work in the various sections will proceed from 9.30 A.M. to 2 P.M. on all days during the Congress, from Tuesday to Friday inclusive. *During the period of the Congress* some of the largest private houses in London with interesting collections of pictures will be thrown open to visitors.

THE BOTTLE IN THE PATH.

"A MOTHER" has addressed to one of our contemporaries a timely and sensible appeal against the practice of throwing away or breaking bottles on the beach at seaside resorts. She quotes the case of her own child whose foot was very seriously injured by treading on a piece of broken glass thus carelessly thrown aside. Her proposal that this matter should be dealt with by local councils is an eminently practical one. If, as she suggests, appropriate notices were freely exhibited and bins were placed at intervals near the beach for the reception of empty bottles and the like the rambling tripper would have no excuse for leaving such dangerous mementoes in the path of barefoot children. It should not, indeed, be needful to provide such receptacles and any such concession to the careless convenience of individuals must be a mere matter of favour. No one has a right to throw about a public place any object which may cause injury to the passer-by. A prohibitory notice, or as many as may be advisable, with a penalty included, would, however, be no *more than fair in the public interest. It* is well to remember that the dangerous practice referred to is not confined to the sea beach. How commonly does one meet with broken glass and bottle-ends recklessly strewn about on suburban roadways. The feet of horses are in constant danger from this cause. The care of roads and streets is generally understood to be included among the duties of borough councils. It seems to us, therefore, not a little strange that means are not used by these local authorities *to prevent this culpable* and mischievous habit of throwing glass in the way of passengers and traffic. A by-law on the subject, especially after being suitably illustrated with a few convictions, would materially aid in assuring the safety of a long-suffering population and its four-footed servants.

THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

AT a recent meeting of this society, the President, Dr. F. W. Pavy, LL.D., F.R.S., announced that the society had been honoured by a gracious intimation that His Majesty the King would grant its representatives an audience for the presentation of the society's loyal address of condolence and congratulation. Accordingly the President, with Lord Lister (the mover of the address) Sir William S. Church, and Mr. J. Warrington Haward (honorary treasurers), Sir Thomas Barlow and Mr. Clinton T. Dent (honorary secretaries), and Mr. A. Pearce Gould (late honorary secretary), attended at St. James's Palace on March 20th. The deputation was honoured by a private audience, His Majesty receiving the address personally and handing the President the following reply :—

> I have received with the greatest satisfaction the loyal and dutiful address which you have laid before me to-day, expressing devotion to my throne and person and sympathy with me and my Royal consort in our grief.
>
> The spontaneous expressions of loyalty and goodwill which have reached me from all parts of my empire and all classes of my subjects have been a powerful encouragement to me in undertaking the cares and labours surrounding the throne which I have inherited from my beloved mother; and with her example before my eyes I shall spare *no effort* to secure the continuance of the prosperity which attended her reign.

The President, with the proposer and seconder of the address, kissed hands, and the other members of the deputation were introduced to His Majesty by the President. A few days later the following letter was received :—

> Buckingham Palace,
> 27th March, 1901.
>
> GENTLEMEN,—I have the honour to inform you that I have submitted to the King your *letter of* the 21st *inst.*, and in reply I am commanded to say that His Majesty is pleased to accede to the request contained in it to grant his patronage to the Royal Medical and Chirurgical Society.
>
> I am, Gentlemen, your obedient servant,
> D. M. PROBYN, General,
> Keeper of His Majesty's Privy Purse.

Since then the society has been informed that the King would be graciously pleased to add his signature to the roll of the society.

THE OFFICE OF DIRECTOR-GENERAL OF THE ARMY MEDICAL SERVICE.

ON application to the Secretary of State for War we have been courteously informed that "no appointment has yet been made to the post of Director-General, Army Medical Service." The matter is one of great interest to the medical profession as a whole, and we trust that there may not be any prolonged *delay in making the appointment.* The fact that the post has already been vacant for a considerable time has not unnaturally given rise to various doubts and conjectures which it is desirable should be set at rest as soon as possible. We trust, therefore, that the War Minister may see his way promptly to come to a decision and to make public announcement of his decision at an early date.

IT is announced that the following have been appointed on a committee to consider the amendment of the first schedule annexed to the Pharmacy Act, 1868:—The Right Hon. Sir Herbert Maxwell, M.P., F.R.S. (chairman), Mr. Alexander Cross, M.P., Professor T. E. Thorpe, C.B., F.R.S., Professor W. A. Tilden, F.R.S., Dr. Thomas Stevenson, Mr. William Martindale, F.C.S., and Mr. J. H. Harrison.

SIR HENRY E. ROSCOE Vice Chancellor of the University of London, will on July 10th formally open the new Pathological Institute at the London Hospital. Subsequently, in the library of the school, prizes will be distributed to students and nursing probationers.

SIR MICHAEL FOSTER, K.C.B., M.P., will present the awards at the annual presentation of prizes to the students of the medical school of St. Mary's Hospital on Thursday, June 27th, at 4 P.M.

THE annual banquet of the Association of British Postal Medical Officers will be held in the Whitehall Rooms of the Hotel Métropole, London, S.W., on Wednesday, July 3rd, at 7.30 P.M.

THE ROYAL BRITISH NURSES' ASSOCIATION.—On June 9th Sir James Crichton Browne presided at the annual meeting of this association at the Imperial Institute. Mr. J. Langton, the treasurer, presented the financial statement, reporting that the income compared favourably with the receipts of previous years. Of the £1552 received from the café chantant at the Hotel Cecil, £1350 had been invested and the interest would be devoted for the benefit of nurses who might be in need of assistance. Mr. Langton asked for increased support for the Settlement Fund, the object of which is to provide a home for retired nurses unable longer to pursue their calling.

THE ELECTION TO THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ON Thursday, July 4th, the Fellows of the Royal College of Surgeons of England will exercise their privilege of electing to the Council three of their number. As is the case with most other privileges, this is closely associated with a duty, and it behoves all Fellows who appreciate the importance of the trust committed to their charge so to vote as to benefit in the highest degree the science and art of surgery, the medical profession, and the public at large. It may safely be said that no other medical body in this country has more influence on the trend of medical education as the Royal College of Surgeons of England, and this is due both to the large number of its *alumni* (for there are 20,000 Members of the College and almost 1500 Fellows) and to the position it has attained in the estimation of the people.

The government of this large and important corporation is vested in the Council of 24 members who must be Fellows. They are elected by the whole body of Fellows and therefore the control of the College is practically in the hands of the Fellows should they choose to exercise it, for every year there are at least three vacancies on the Council to be filled at the election in July, and if the Fellows were alive to their opportunities and responsibilities they could have a real voice in the government of the College, but many of them know little and care less of what occurs in Lincoln's Inn Fields, and the many crying needs of the College are unfulfilled and neglected. At one time there was some excuse for the practical non-participation of the great body of the Fellows in the election of the Council, for less than 20 years ago it was necessary for the Fellow to attend in person to record his vote, and, being much occupied with many calls on their time, it was not surprising that a large proportion of even the London electors were unable to be present at the College at some time in the two hours during which the poll was open; and for country Fellows voting was still more difficult, for the journey to and from London in many cases occupied the greater part or even the whole of the day. Now, however, the arrangements are very different, for the Fellow can vote by post, and so very easy has it been made for him that it is now not even necessary for him to apply for a balloting paper, for it is sent unasked to every Fellow of the College in the United Kingdom whose address is known. This paper has merely to be marked, signed, and the signature witnessed, and the paper posted to the secretary, but so apathetic are the Fellows, so regardless of their privilege, that at no election have more than half the Fellows recorded their votes. Full and clear directions are given with each balloting paper, and the Fellows are a highly educated body of men, yet at every election some votes are lost by incorrect fulfilment of the very simple rules laid down. Balloting papers are returned without signature, without any indication as to the candidates voted for, or with too many names.

There is yet another and a most striking indication of the apathy of the Fellows with regard to the work of the College. A few years ago it was felt that meetings of the Fellows should be held from time to time at which subjects of importance to the Fellows and to the College could be discussed and at which the Council could lay before the Fellows important matters for the purpose of receiving their opinion. After years of work the institution of regular meetings of the Fellows apart from the Members of the College was obtained from the Council, and two meetings were appointed to be held every year in January and July. For a few meetings the numbers present and the subjects discussed justified the establishment of the meetings. The numbers, however, steadily dwindled and for the last three years it has been found impossible to obtain the presence of the 30 Fellows necessary to form a quorum. Time after time the President, the Vice-Presidents, and a few Members of Council and other Fellows have assembled in the theatre of the College and waited for a quorum, but they have waited in vain. As a result the Council has decided to do away with the January meeting, and it is possible that the July meeting also may be discontinued if the Fellows do not display more desire for its existence. The Council would still possess the power of calling a meeting of the Fellows when it desired to lay before them any subject of special importance, but this is very different from regular meetings.

The Fellows form a large body of highly educated and trained surgeons and their collective wisdom on matters both of College politics and the affairs of the whole profession would be well worth obtaining. There are especially two subjects on which the Fellows should express an opinion, both for the guidance of the Council and for the sake of the medical profession. The first matter on which their opinion is desired is the question of the representation of the Members of the College on the Council. It may be said that the Fellows have already voted on this subject. It is true that four years ago the Council sent round to the Fellows a series of questions relating to the representation of Members and that a majority of the replies received were inimical to the granting of any representation, but the total number of answers received was so small that no true opinion of the real feeling of the whole body of Fellows can be based on the voting of a small minority. We do not propose on this occasion to recapitulate the arguments in favour of granting to the Members some share at least in the government of the College; these arguments have often appeared in the pages of THE LANCET and must be fresh in the minds of many of our readers, but we would urge that in the decision of this question the voice of the whole body of Fellows should be heard. The other subject on which the Fellows should assist the Council in coming to a decision is the question of the connexion of Members of the College with medical aid associations. Again and again at the annual meeting the Members have called upon the Council to put forth a pronouncement that it considers the holding of an appointment under a medical aid association as a sufficient cause for the recall of the diploma and thus to follow in the footsteps of other colleges. On this point also the ideas of the Fellows should be of the greatest value and they should feel that they are called upon by their position to give to the Council the benefit of their opinion.

Unless the Fellows by one means or another indicate what they think and feel on these important points it is not possible for the Council to decide on them in a manner consonant with the ideas of the body of Fellows as a whole.

The three members of the Council who this year retire by rotation are Mr. N. C. Macnamara, Mr. A. W. Mayo Robson, and Mr. W. Watson Cheyne. Mr. Macnamara does not intend to offer himself for re-election, but Mr. Mayo Robson and Mr. Watson Cheyne will again be candidates. Mr. Mayo Robson is one ofthe most widely-known of provincial surgeons and no better representative of the provincial Fellows could be found. Mr. Watson Cheyne is recognised as one of the most able exponents of antiseptic as opposed to aseptic surgery. Both of these gentlemen have done good work for the College during the time they have been on the Council, and the Fellows cannot do better than re-elect them as will probably be the case. There are six other candidates: Mr. H. H. Clutton of St. Thomas's Hospital, Mr. Jordan Lloyd of Birmingham, Mr. Clement Lucas of Guy's Hospital, Mr. J. H. Morgan of Charing Cross Hospital, Mr. C. Mansell Moullin of the London Hospital, and Mr. Bland-Sutton of Middlesex Hospital. The only one of these who is a provincial candidate is Mr. Jordan Lloyd of Birmingham, and as this important medical school is unrepresented on the Council there is much to be said in favour of Mr. Jordan Lloyd's claims, but there are already five provincial representatives on the Council and it will probably not be thought desirable that provincial Fellows should be represented by more than five members out of the 24. St. Thomas's Hospital has at present only one representative, and as it is a large and important school it would not be unreasonable that Mr. Clutton should be elected. He is widely known as an able surgeon and an energetic administrator. Mr. Bland-Sutton comes from Middlesex Hospital, which has already two representatives, and therefore, considering the size of the school, it would be certainly unreasonable at present to increase its representation. Guy's Hospital, with its two representatives, may perhaps claim to have a third, and no fitter surgeon could be chosen than Mr. Clement Lucas, but it seems undesirable to increase the number of Fellows from any one school while other hospitals are unrepresented. Mr. Morgan comes from Charing Cross Hospital, which for some years has not been represented on the Council, and this is in itself a strong argument in his favour. His appointment would be a distinct gain to the Council. Mr. Mansell Moullin's election would give another representative to the London Hospital, but this would hardly be unfair, as the school is large.

We hope we have said sufficient to induce the large majority of the Fellows to exercise their power of voting at the approaching election, for we believe that the wider the interest they take in the affairs of the College the better will it be for the College itself and for the whole medical profession.

REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD FOR 1899-1900.

I.

MR. W. H. POWER in his report to the President of the Local Government Board devotes a paragraph to the plague and calls attention to two papers by Dr. R. Bruce Low which are printed amongst the appendices. Dr. Bruce Low has devoted special attention to the course of the spread of the disease, and the full results of his researches will be published at some future time in a separate form. Of the appendices relating to the plague which are published in the present volume, the first (Appendix A., No. 14) is a "summary of the progress and diffusion of plague during 1899," while the second is a memorandum on the precautionary measures which were taken in 1899 to prevent the importation of bubonic plague into England and Wales and on certain cases reported as plague or suspected plague.

During the year 1898 the parts of the world which suffered most from plague were China, India, Japan, some parts of Asiatic Russia, Arabia, East Africa, and Madagascar. During the same year three deaths from plague took place in Vienna, but these cases derived the infection from the bacteriological laboratory and there was no further spread of the disease in Austria. During the year 1899 the area of infection was largely increased, places in Europe, Asia, Africa, America, and Australia all coming within its sphere of influence.

China suffered greatly, but statistics as to the numbers affected and as to the number of deaths are not accurate, for Chinese methods of reporting and registration are most unsatisfactory—a fact which will cause little surprise. Hong-Kong has not been free from the plague since the year 1894, but the mortality has varied within very wide limits. The number of deaths reported have been as follows: in 1894, 2550; in 1895, 36; in 1896, 1078; in 1897, 18; in 1898, 1175; and in 1899, 1415. Japan did not suffer from any great outbreaks and the cases were apparently imported from China—most of them from Hong-Kong. The inhabitants of Formosa suffered considerably, the Japanese official statement showing that there were no less than 2633 cases and 1974 deaths. An outbreak also occurred in the Philippine Islands, and over 60 cases are said to have occurred in the Sandwich Islands. Numea in New Caledonia was affected towards the end of the year, the first sufferers being Kanakas and Tonkinese labourers. The disease afterwards (in 1900) spread to the nickel mines of Nepoui which are worked by convict labour. It was towards the end of the year 1899 that sporadic cases were first diagnosed at Adelaide, South Australia, and at Sydney in New South Wales, and about the beginning of the year 1900 cases were recognised at Melbourne in Victoria and at Brisbane, Rockhampton, Townsville, Cairns, and Ipswich in Queensland. A few cases also occurred in Western Australia and a single one was reported from New Zealand. At the Straits Settlements the disease occurred as early as May, 1899. At Penang no Europeans were affected, a few of the sufferers were Malays, but most of them were Chinese. It is thought that the infection was brought from South China and it is known that a large number of coolies arrived thence shortly before the outbreak. The number of deaths recorded was 37. At Singapore there was no epidemic, but a few cases were landed from ships.

A severe epidemic visited India. The plague was first recognised in the city of Bombay in the year 1896 and from that date the place has never been free from it. During the summer fewer cases have occurred. The mortality has been highest during the month of March and lowest during the months of June and July. The following table gives the number of cases and of deaths reported and the case-mortality per cent. for the years 1896 to 1899:—

Year.	Plague cases	Plague deaths.	Case-mortality per cent.
1896	2,530	1,801	71·1
1897	11,963	10,232	85·7
1898	19,863	18,160	91·2
1899	19,484	15,830	81·3
Total	53,840	46,023	85·4

The Presidency of Bombay has suffered severely and the number of those affected has increased year by year since 1896. This will be readily seen in the subjoined table which may be profitably compared with the corresponding one given above for the city of Bombay. The table shows the number of reported cases and of deaths and the case-mortality in the Presidency of Bombay (not including the city of Bombay) for the years 1896 to 1899, both inclusive.

Year.	Plague cases.	Plague deaths.	Case-mortality per cent.
1896	367	273	74·3
1897	49,125	36,707	74·7
1898	90,506	68,061	75·2
1899	131,794	101,485	77·0
Totals ...	271,792	206,526	75·8

The districts which suffered most severely were Belgaum, Dharwar, Karachi, Kholapur, Poona, Satara, Surat, Thana, Nasik, and Bijapur. In the city of Poona there were no less than 5316 deaths in five weeks and during the epidemic the total mortality from the disease was over 10,000. In Karachi there were over 2000 deaths. In the city and suburbs of Calcutta there were over 3000 cases and 2745 deaths in the year 1899, whereas during the previous year the number of the recorded deaths from the disease amounted to no more than 192. In the Presidency of Bengal during the year 1898 only 16 deaths from plague were officially reported from the district not contained in the city of Calcutta, and during the year 1899 outbreaks were reported from Howrah, from Saran, and from a few other places, the number of cases being 652, and the number of deaths 505. Towards the end of the year there was a severe outbreak at Patna, and during the first half of the year 1900 over 17,000 deaths were reported from that district alone. In the Central Provinces the number of reported deaths during the year 1898 was 129, and with the exception of four, all these cases occurred in the Wardha district. In the year 1899 only 65 fatal cases were reported from Wardha, but the Nagpur district was much more affected, the number of deaths being 460, of which 202 were reported from the city of Nagpur. According to the accounts received the Native States of Central India suffered but little. The Madras Presidency was affected during the early part of the year 1899, the disease being most prevalent in those districts which border on the States of Hyderabad and Mysore, in both of which plague was at the time epidemic. In the city of Madras itself 11 cases and four deaths were reported during the year, but the total number which occurred in the Presidency amounted to no less than 2460 cases, of which 1655 ended fatally. In the State of Hyderabad during the year 1899 there were 5271 cases and 4242 deaths, and of the latter above 2000 occurred during the month of October alone. In the State of Mysore the districts chiefly affected were the city and district of Bangalore, the city and district of Mysore, and the Kholar goldfields. Plague was epidemic in the State during the year and the number of deaths which had occurred up to the end of the year 1899 amounted to 15,697. The disease reappeared in the winter of 1899-1900. Assam has escaped lightly: four fatal cases only were reported in the year 1899 and there has been apparently no spread of the disease. From Burma a single imported case was reported from Rangoon and for Baluchistan three fatal cases only have been notified; there has been no epidemic in either country.

In Persia plague appeared in May, 1899. 40 cases were reported, but in August the outbreak was over. In Mesopotamia four or five cases were recognised.

In Arabia several districts were infected during the year 1899. A case of plague from Karachi is said to have set up an epidemic at Muscat, where 600 deaths occurred. During March and April there were 230 fatal cases at Mattrah. Early in 1900 there was an epidemic at Aden which caused 575 deaths. From Aden the disease was carried by refugees to Berbera in British Somaliland, on the east coast of Africa. Only two fatal cases occurred, the refugees being kept under observation at the Berbera sanitary station. The name of the sanitary officer at Berbera, which is not given in the report, deserves to be put on record. It is probable that his prompt action was the means of saving the colony from a great catastrophe. Assyr in Arabia is a district through which pilgrims to Mecca constantly pass. It was infected with plague in 1899, as it was in many previous years, and the disease must be regarded as being endemic there. Dr. Bruce Low points out that the place is consequently a constant source of danger to the outside world. Djeddah, the chief port of Hedjaz, suffered from plague during the years 1896–97–98, and again during 1899, when its origin was traced to pilgrims. Records as to the number of fatal cases are not to be relied on, and according to the sanitary inspector of the district the numbers given were much understated. It seems, also, that early cases of the plague were called influenza. The Turkish authorities have not published official accounts of the outbreak and details are entirely wanting.

In Africa many places have been affected—Egypt, British and German East Africa, Lorenço Marques, the Transvaal (one imported case which proved fatal), Mozambique, and Grand Bassam (a French possession in East Africa). In May, 1899, it was officially recognised that plague was present in Alexandria, and during the year 93 cases were certified, the number of deaths being 45. Of the cases 65 occurred in natives, 25 in Greeks, two in Frenchmen, and one Italian only was affected. The origin of the outbreak could not be traced. In May, 1900, the disease reappeared. The first cases were traced to people engaged in rag-picking.

In the Portuguese colony of Lorenço Marques plague is supposed to have occurred first in a Parsee whose death was certified as having been due to "galloping consumption." The infection is supposed to have been imported from Madagascar. The Portuguese authorities were not desirous to spread exact knowledge as to the occurrence and incidence of the disease; the Governor-General assured the foreign Consuls that there was no plague in the district, and the medical men were forbidden to certify that patients had the plague.

Madagascar suffered from outbreaks of the disease in the years 1898 and 1899; no details of the epidemic are available, but it is said that only one European has been affected.

At the Island of Réunion cases of *lymphangite infectieuse* were reported in April, 1899, and a question arose as to the exact nature of the disease. Dr. Thiroux, a colonial medical officer, obtained the opinion of Dr. Roux of the Pasteur Institute, who succeeded in finding the true plague bacillus. From this fact Dr. Thiroux concluded that *lymphangite infectieuse* and plague are identical. On this matter Dr. Bruce Low pronounces no opinion.

It has been already mentioned that plague has been called "galloping consumption," and it may be convenient here to give other names by which the disease has been lately called in various parts of the world. It seems probable that in Mauritius it has been diagnosed as "malarial fever." In Lisbon it was at first called "the Indian typhoid." In Paraguay it was named "malarial fever" and "typhus." In Brazil it was called variously "pernicious lymphangitis," "adenitis lymphatica," and "yellow fever with buboes," and at Rio Grande do Sul it had amongst other names that of "virulent influenza." Cases of plague appear also to have been diagnosed as "beri-beri."

A brief reference must be made to the course of the plague as it affected America. Few cases appeared in the northern part of the continent. A single case was imported to New York and several were landed at Port Townsend. In neither of these instances was there any general spread of the disease. At San Francisco a few cases occurred in the Chinese quarter in March, 1900, and some deaths ascribed to pneumonia which occurred in Montana were possibly cases of plague. From Mexico accounts of a mutually contradictory nature have been received. There seems little doubt that cases occurred at Buenos Ayres, and that the infection was derived from Oporto. Cases occured at Rosario in the Argentine Republic in January, 1900, but the source of infection is not known. From Rosario the plague was conveyed to Cape Town by means of a forage transport. Buenos Ayres was also affected in December, 1899, and January, 1900, but its existence there was at first denied by the authorities. In Brazil a few cases occurred in Santos in October, 1899, and at San Paulo later in the year. Rio de Janeiro was affected later and 130 deaths from the disease were reported.

In Europe the country chiefly affected in 1899 was Portugal and full accounts of the outbreak in Oporto have been already published, but it has yet to be found by what means the plague reached the country, and although various surmises have been formed they do not appear to have been founded on any positive evidence. The Local Government Board received from the Foreign Office on August 15th, 1899, copies of telegrams notifying the outbreak in Oporto. On the day following the Medical Department of the Local Government Board obtained the sanction of the Board to conduct a port sanitary survey. Three members of the staff, Dr. Thompson, Dr. S. M. Copeman, and Dr. R. J. Reece, were instructed to visit some of the ports at once. Soon afterwards Dr. G. S. Buchanan and Dr. D. Mair were appointed to the survey staff, and Dr. F. St. G. Mivart and Dr. Johnson were instructed to hold themselves in readiness to render additional assistance in case of need. Information was at once sought of the Board of Customs as to which of the English and Welsh ports were most frequently in communication with Portugal and it was found that 16 ports had communications with Oporto and five more with other Portuguese ports. It was thought, considering the possibility of the extension of plague to Spain, that ports trading with all parts of the Peninsula ought to be examined. This added 18 to the number to be inspected and brought up the total number of port and riparian authorities concerned to 39. To all these authorities general and particular advice was given by the inspectors. Attention was called to the necessity for inspecting the shipping and for examining medically those who arrived from infected ports. Further, the necessity for isolation accommodation and for means of disinfection was insisted upon, and the method of disposal of the bodies of patients who might die from plague was discussed. Conferences were held as to the destruction of rats. In some cases the Board on the advice of their inspectors wrote to the port authorities calling their attention to certain sanitary improvements which ought to be made without delay, and as a result prompt action was taken in many cases. A circular letter was sent on August 16th to the port sanitary authorities informing them that there was an epidemic of plague at Oporto and directing special attention to all vessels arriving from that port.

During the course of the survey made by the medical inspectors some of the Customs officers did not genially coöperate with the port authorities, and it was found necessary to communicate with the Board of Customs, who sent a circular to their officers expressing surprise at the past action of some of their number and a clear expression of the certainty which the Board entertained that no trouble arisising from that cause would occur again. The next little difficulty which arose was as to the interpretation of one of the Local Government Board's own Orders (the Order of Nov. 9th, 1896). The questions were: What was an infected port? What was a suspected vessel? What was to be done in case of sick persons who were sent over as British consular passengers but who had no medical certificate? In regard to the latter question the Board of Trade had to be consulted and it was settled that in future medical certificates should be sent in all cases. Another matter which it was found necessary to decide was the meaning to be attached to the word "voyage." It was evident that a ship arriving from a foreign port might in the ordinary course of trade land part of her cargo at one English port and then pass on to another port. A conference was held with the representatives of the Customs, and it was settled that in such a case a vessel at the second or third port of destination should still be held as coming "from foreign," and that the Customs officers should thereupon inform the port medical officer of the arrival of such a ship. The port medical officer on his part was to keep the Customs authorities informed as to what countries were regarded as infected.

Measures were also taken with a view to supply M. Haffkine's prophylactic. With this view consultations were held with officials of the India Office and arrangements were made that a supply of the protective fluid should be sent from India. M. Haffkine happened to be at the time in England, and the medical officers of the Local Government Board received full information from him as to the details of his method of inoculation. A brief description of the prominent symptoms of the plague was drawn up for the use of the captains of those ships which do not carry surgeons on board, and this leaflet is now incorporated in the official log-book. In order to provide for the immediate recognition of any cases of plague which might by chance escape the vigilance of the port sanitary authority, or might occur after the landing of sailors, an officer of the Board inspected the seamen's boarding- and lodging-houses which are situated near the London docks and conferred with the authorities of the chief London hospitals and with the medical officer of the London County Council, and also with the Metropolitan Asylums Board. The Foreign Office were advised by the Local Government Board that it would be well if arrangements were made by which the British representative on the Egyptian Sanitary Board could supply information to the Board as to what diagnoses were arrived at in the case of persons at Moses' Well who were suspected of being infected with the plague. Moses' Well, it may be said, is the Egyptian sanitary station at the head of the Red Sea. In consequence of the absence of any proper official means of communication unnecessary trouble was caused; in one case, for example, the Board only heard indirectly and after a long interval that some patients who had been diagnosed as suffering from plague had not had the disease at all.

It will be readily seen that the measures taken by the Medical Department of the Local Government Board for the prevention of plague in this country were quickly and thoroughly carried out. The arrangements made in conjunction with the Board of Trade and the Customs will also be of use in ensuring the smooth working of any measures which may in future be rendered necessary by any threatened invasion of epidemic disease. It is a matter for congratulation that during the year 1899 no case of plague occurred in this country, and the fact that a considerable number of persons were detained as "suspects" by the port medical officers, as Mr. Power says, "is evidence of the strict scrutiny which they exercised over the arrival of people coming from infected places."

THE CORONERS' SOCIETY OF ENGLAND AND WALES.

The annual banquet of the Coroners' Society of England and Wales was held at the Holborn Restaurant, London, W.C, on June 6th, the President, Mr. Sidney Hacker, coroner for Devonshire, being in the chair. At the conclusion of the banquet, after the loyal toasts had been duly honoured, "The Coroners' Society" was proposed by Mr. Thomas Wakley, jun., who pointed out that the society was founded in 1846, and that during the first year there were 56 members, whereas the number at the present time was 270—practically a five-fold increase during the 55 years of its existence. The society was first formed simply with a view to safeguard the interests of coroners. This, though a very useful and worthy object, was limited to a class, but what was intended at first to be merely for the benefit of a few had come to be of value to the whole community. Amongst other things the work of the society had resulted in much greater uniformity in the carrying out of their duties by coroners in England and Wales and this necessarily meant a great gain to the community. The first president of the society was Mr. (later Sir) John Humphreys who continued in office for many years. He was succeeded by Mr S. F. Langham who filled the combined position of president and treasurer. On his retirement from these offices a biennial presidentship was established which continued to the present time. It was pleasing to think that Mr Langham, on retiring from the coronership of the City of London, the duties of which he had ably discharged for very many years, had been granted by the corporation a pension of £600 per annum, this being the first time a pension had been given. The Coroners' Society, through its council and by the action of individual members, had practically initiated the erection of proper mortuaries, chambers for post-mortem examinations, and coroners' courts, and by means of representations founded on riders to verdicts by juries had brought the necessity for such to the notice of local vestries and parish councils. The society was recognised by the departments of State as a representative body able to afford trustworthy assistance in such matters as statistics, prevention of deaths and accidents, &c. In 1893, in consequence of representations made by the society to the Home Office, the Secretary of State gave directions that any person who was accused of having caused the death of another person should, if he so desired, appear before the coroner, hear the evidence of witnesses, and give evidence himself. Many had availed themselves of this opportunity and in some instances had cleared themselves of the charges brought against them. Practically the society was the pioneer of the subsequent Criminal Evidence Act of 1898. The society, moreover, had been largely instrumental in getting carbolic acid placed on the schedule of poisons, and it had assisted towards the provision of regulations for the greater care of infants, the protection of children from fire by the use of fire-guards, the improvement of dwellings, sanitary and otherwise, the use of safer lamps for paraffin oil, the erection of bridges at level crossings, the inspection of workhouses and laundries, and other important matters. The society, the speaker said, was, he understood, now engaged with a view to lessen the number of uncertified deaths, and also with regard to the registration of still-births, undertakings in which everyone must wish it success. There had just come to light at Birmingham another gruesome object-lesson of the need for further legislation There could be no doubt that by the more efficient, diligent, and complete investigations made by coroners into the causes of death much had been done to safeguard and to preserve human life, and this excellent result was doubtless very largely due to the influence of the society and the example set by its members. In conclusion, Mr. Wakley said that he felt that the honour of proposing the toast had been bestowed upon him because he happened to be a descendant of one who, if he might say so without impropriety, was in his time a respected and somewhat noteworthy coroner—one whose influence as coroner both on the ancient and honourable office itself and on the welfare of the people had been, he ventured to think, wholly for good.—Mr. Sidney Hacker, the President, replied.—The other toasts were "The Imperial Forces," proposed by Mr. Henry White, coroner for Winchester, and responded to by Captain H. Kendall and Surgeon-Lieutenant Colonel Danford Thomas, M.D, coroner for London and Middlesex; "Our Guests," proposed by Mr. H. J. Robinson, coroner for Lancashire, President elect of the society, and responded to by Sir Franklyn Lushington, chief police magistrate for London, who contrasted the office of coroner, founded certainly not later than the time of King Alfred the Great, with that of the civic magistrate which came into existence in the early part of the reign of Queen Victoria, and Mr A. O. Mackellar, chief surgeon to the metropolitan police, who referred feelingly to the sad death of his colleague, Mr Thomas Bond, which had occurred that morning; and "The Officers of the Society," proposed by Mr J. C Malcolm, coroner for Leeds, and replied to by Mr. A. Braxton Hicks, coroner for London and Surrey, the secretary of the society. A vote of thanks was given to Mr Walter Schroder, deputy coroner for London and Middlesex, who had made all the arrangements for the dinner, and was briefly acknowledged by him. In the course of the proceedings a loving-cup was presented by the retiring President, Mr. Hacker, to the society in token of his period of office, and we may add that a coroner's robe was presented to Mr. Hacker.

NEW OPERATING THEATRE AT CARDIFF INFIRMARY.

A new operating theatre in connexion with the Cardiff Infirmary was formally opened on June 6th by Mr. Edmund Owen, F R C S Eng, senior surgeon to St Mary's Hospital.

Although it had been felt for some years that a new theatre was an absolute necessity the management committee of the infirmary, having an ever increasing revenue debt before them, very properly refused to burden the institution still further upon its capital account. Early in the year 1899 Mr. Thomas Webb of Tunbridge Wells, a director of the Ocean Colliery Company of Cardiff, came to the relief of the committee with the offer of a donation of £1000 towards the erection and equipment of a new theatre in memory of his wife, and the architect to the infirmary, Mr. Edwin Seward, F.R.I.B.A., of Cardiff, prepared plans for the building. Upon their completion it was found that if the new theatre was to satisfy the requirements of the present day the cost would be at least £1500, and upon this fact coming to the knowledge of Mr. Webb he very generously increased his contribution to that sum.

The alterations and additions to the building give to the infirmary two operating theatres, a room for the surgical staff, two ante-rooms for the administration of anæsthetics, and a students' room, all on the ground floor and within 30 feet of the casualty entrance to the institution and only about 10 feet from the lift. In the old theatre and in the students' room the floors have been reconstructed and covered with terrazzo, the walls have been painted, electric lights have been installed, and a sink has been fixed in the theatre provided with fittings similar to those in the new theatre described below. The full size of the new theatre is 18 feet by 25 feet, but this area is reduced to 18 feet square by the three-tier students' gallery, which is divided from the floor of the theatre by a single iron rail and is approached from the students' room by a separate passage. The height of the building from the floor to the inside of the roof ridge is 23 feet. The whole slope of the roof upon the north side is glazed along its entire length with fixed glass; the underside of the slates upon the other slope is finished with Keen's cement painted white. Three metal-framed casement windows are placed in the north wall of the theatre. Each of the ante-rooms is divided from the adjoining theatre by sliding doors running upon an iron carrier above and in a groove at the floor level. The floors are laid with terrazzo and in the theatres there is a slight fall towards a currented channel in the terrazzo which in turn discharges into the open air upon a channel leading to a trapped gully. The walls are lined to a height of seven feet from the floor with light green glazed bricks; above this dado in the new theatre there are white glazed bricks to the ceiling slope, and elsewhere the walls are covered with Keen's cement finished with hard white paint. All corners are rounded and ledges are generally avoided; there are no architraves to windows or doorways. In the gable wall of the new building is placed a Blackman's extraction fan about 12 inches in diameter operated by an electro-motor and capable of rapidly changing the whole of the air in the theatre. Inlet ventilators with hit-and-miss internal gratings and with an area of 18 inches by nine inches are fixed a few inches above the floor-level in all the rooms. In front of the principal of these openings there are hot-water radiators so constructed that they will swing at right angles to the wall, and as each radiator has a distinct connexion with the hot-water pipes the temperature of the building can be regulated at will. Artificial lighting is provided with incandescent electric lights, the central light over the operating table being a combination of 16 16-candle power lamps. In each theatre and in the staff room there is a white glazed sink; the water fittings of white metal enable hot, cold, or tepid water to be drawn off or sprayed from distinct taps. There are no pedal fittings, but over the handles of the taps, which are fixed at right angles to the water-pipes, there are placed loose white metal coverings which can be removed and sterilised each time they are used. In the dividing wall of the two theatres and opening into either is an autoclave made by Sulzer of Winterthur for the sterilisation of instruments or dressings. An instrument case with glass doors and glass shelves is to be placed in one of the ante-rooms.

A great deal of painstaking care appears to have been bestowed in matters of detail upon the construction of the building and the staff are to be congratulated upon having the coöperation of an architect who has realised the necessity for providing a building which shall be entirely hostile to the propagation of micro-organisms. The sterilised loose covering for the water taps is a novelty and will probably be found an improvement upon the pedal fittings. It will be a great comfort to the operating surgeon to know that his instruments and dressings have been subjected to the thoroughly effectual sterilisation of Sulzer's autoclave. There appears to be only one detail capable of improvement and that relates to the sliding doors between the ante-rooms and the theatres; the grooves in which these doors run will undoubtedly be the receptacle for dust and dirt and will be extremely difficult to keep clean.

DINNER TO SURGEON-GENERAL JAMESON, C.B.

AT a meeting recently held it was determined to invite Surgeon-General Jameson, C.B., to a complimentary dinner offered to him by his professional brethren. Surgeon-General Jameson has acted as Director-General of the Army Medical Department for the past five years and has had to discharge during that period duties involving the greatest responsibility, especially in connexion with the medical requirements of the war in South Africa.

Sir William Church has consented to take the chair and the dinner will probably take place in the latter part of July. An executive committee has been appointed to make the necessary arrangements, and communications will be received by the honorary secretary, Mr. Cuthbert Wallace, F.R.C.S. Eng., 75, Lambeth Palace-road, S.E.

The proposal has been cordially accepted by the President of the Royal College of Physicians of London (Sir William S. Church, Bart.), the President of the Royal College of Surgeons of England (Sir William Mac Cormac, Bart., K.C.B.), the President of the Royal College of Physicians of Edinburgh (Dr. Fraser), the President of the Royal College of Surgeons of Edinburgh (Dr. Dunsmure), the President of the Royal College of Physicians of Ireland (Sir Christopher Nixon), the President of the Royal College of Surgeons in Ireland (Mr. Thomas Myles), the President of the Faculty of Physicians and Surgeons in Glasgow (Dr. Finlayson), the President of the General Medical Council (Sir William Turner, K.C.B.), the Rt. Hon. Lord Lister, F.R.S., Sir Thomas Barlow, Bart., K.C.V.O., Sir Douglas Powell, Bart., K.C.V.O., Sir Thomas Smith, Bart., Sir Joseph Fayrer, Bart., K.C.S.I., Sir Frederick Treves, K.C.V.O., C.B., Sir John Batty Tuke, M.P., Sir Hector Cameron, Sir Dyce Duckworth, Sir William Thomson, C.B., Dr. F. W. Pavy, F.R.S., Dr. Patrick Heron Watson, Mr. Willett, Professor McCall Anderson, Mr. J. Langton, Mr. H. T. Butlin, Mr. Howard Marsh, Mr. A. A. Bowlby, C.M.G., Professor John Chiene, C.B., Mr. C. Stonham, Mr. W. Watson Cheyne, C.B., F.R.S., Mr. G. H. Makins, C.B., Mr. John Morgan, Dr. Allchin, Dr. Anderson, Dr. Bowles, Dr. Shore, Mr. Alfred Cooper, Dr. Farquharson, M.P., Dr. Philip Frank, Mr. Reginald Harrison, and Professor D. J. Cunningham, F.R.S.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6965 births and 3336 deaths were registered during the week ending June 8th The annual rate of mortality in these towns, which had been 16·8, 16·7, and 16·3 per 1000 in the three preceding weeks, further declined last week to 15·2. In London the death-rate was 14·2 per 1000, while it averaged 15·8 in the 32 large provincial towns. The lowest death-rates in these towns were 7·9 in Derby, 12·2 in Brighton and in Bristol, 12·6 in Cardiff, and 12·7 in Blackburn; the highest rates were 18·8 in Halifax, 19·1 in Norwich, 19·4 in Oldham, 19·7 in Nottingham, and 21·2 in Gateshead. The 3336 deaths in these towns included 320 which were referred to the principal zymotic diseases, against 386 and 360 in the two preceding weeks; of these 320 deaths, 91 resulted from measles, 75 from whooping-cough, 57 from diarrhœal diseases, 49 from diphtheria, 32 from scarlet fever, and 16 from "fever" (principally enteric). No death from any of these diseases was registered last week either in Leicester, Preston, or Huddersfield; in the other towns they caused the lowest death-rates in Croydon, Brighton, and Derby, and the highest rates in Swansea, Bolton, Blackburn, Sunderland, and Gateshead. The greatest mortality from measles occurred in Nottingham and Bolton; from whooping-cough in Swansea, Wolverhampton, and Sunderland; and from diarrhœal diseases in Plymouth and Burnley. The mortality from scarlet fever and that from "fever" showed no marked excess in any of the large towns. The 49 deaths from diphtheria included 15 in London, eight in Liverpool, five in Sheffield, three in Blackburn, and three in Leeds. No fatal case of small-pox was registered last week in any of the 33 large towns; and only one small-pox patient was admitted during the week into the Metropolitan Asylums Hospitals and remained under treatment on Saturday, June 8th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2462, against numbers increasing from 1522 to 2352 on the six preceding Saturdays; 314 new cases were admitted during the week, against 323, 341, and 318 in the three preceding weeks. The deaths in London referred to diseases of the respiratory organs, which had been 249, 191, and 240 in the three preceding weeks, declined again last week to 187, and were 61 below the corrected average. The causes of 27, or 0·8 per cent., of the deaths in the 33 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Leicester, Salford, Hull, Newcastle, and 12 other smaller towns; the largest proportions of uncertified deaths were registered in Manchester, Bradford, Sunderland, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·7 and 20·1 per 1000 in the two preceding weeks, further declined again to 19·6 during the week ending June 8th, but showed an excess of 4·4 per 1000 over the mean rate during the same period in the 33 large English towns. Among these Scotch towns the death-rates ranged from 13·7 in Paisley and 13·8 in Aberdeen to 20·1 in Leith and 20·4 in Glasgow. The 625 deaths in these towns included 48 which were referred to whooping-cough, 21 to measles, 18 to diarrhœa, seven to diphtheria, six to "fever," one to small-pox, and one to scarlet fever. In all, 102 deaths resulted from these principal zymotic diseases last week, against 89, 94, and 97 in the three preceding weeks. These 102 deaths were equal to an annual rate of 3·2 per 1000, being 1·7 per 1000 above the zymotic death-rate during the same period in the 33 large English towns. The fatal cases of whooping-cough, which had been 40 and 47 in the two preceding weeks, further increased last week to 48, of which 25 occurred in Glasgow, 11 in Edinburgh, six in Dundee, and four in Leith. The deaths from measles, which had been 19 and 17 in the two preceding weeks, rose again to 21 last week, and included 13 in Glasgow, three in Edinburgh, and two in Greenock. The fatal cases of measles, which had been 30 and 24 in the two preceding weeks, further declined last week to 18, of which 11 were registered in Glasgow, three in Dundee, and two in Edinburgh. The deaths from diphtheria, which had been two and four in the two preceding weeks, further rose last week to seven, and included four in Glasgow and two in Greenock. The six fatal cases of "fever" exceeded the number recorded in any recent week, and included four in Glasgow, where the death from small-pox was also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 101 and 107 in the two preceding weeks, declined again last week to 98, and were slightly below the number in the corresponding period of last year. The causes of 23, or nearly 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which, in the three preceding weeks, had been 25·4, 24·4, and 21·3 per 1000 of the population, as estimated from the results of the recent census, further declined to 20·1 during the week ending June 8th. During the past four weeks the death-rate in the city has averaged 22·8 per 1000, the rates during the same period being 15·3 in London and 20·9 in Edinburgh. The 144 deaths of persons belonging to Dublin were nine below the number in the preceding week, and included nine which were referred to the principal zymotic diseases, against 10, nine, and five in the three preceding weeks; of these five resulted from whooping-cough, two from diarrhœa, and one from scarlet fever. These nine deaths were equal to an annual rate of 1·3 per 1000, the zymotic death-rate during the same period being 1·5 in London and 2·8 in Edinburgh. The fatal cases of whooping-cough, which had been eight, five, and two in the three preceding weeks, rose again last week to five. The 144 deaths in Dublin last week included 21 of children under one year of age and 32 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a decline from the numbers in the preceding week. Six inquest cases and two deaths from violence were registered, and 60, or nearly one-half, of the deaths occurred in public institutions. The causes of six, or more than 4 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

Army Medical Service.

SURGEON-GENERAL A. F. PRESTON, Principal Medical Officer in Ireland, has arrived in London, having as Senior Surgeon-General at home to take temporary charge until the appointment of a new Director-General.

Royal Army Medical Corps.

Captain C. Dalton takes over command of C Company at Aldershot. Surgeon-Captain R. S. Smith, A.M. Reserve, assumes medical charge of troops, field hospital, &c., at Barry Camp. Brigade-Surgeon-Lieutenant-Colonel Wilson, Vol. M S.C., assumes medical charge of the troops, &c., at Irvine Camp.

Volunteer Corps.

Artillery: 1st Shropshire and Staffordshire: Surgeon-Major E. Cureton to be Surgeon-Lieutenant-Colonel. *Rifle:* 1st (Exeter and South Devon) Volunteer Battalion the Devonshire Regiment Surgeon-Lieutenant R. Pickard to be Surgeon-Captain 2nd Volunteer Battalion the Sherwood Foresters (Derbyshire Regiment). Surgeon-Major A. Chawner to be Surgeon-Lieutenant Colonel. 1st Sutherland (the Sutherland Highland): Surgeon-Lieutenant J. K. Tomory to be Surgeon-Captain and to remain Supernumerary. 2nd Volunteer Battalion the Gordon Highlanders: Hugh Gordon Cowie to be Surgeon-Lieutenant.

Volunteer Medical Staff Corps.

The Edinburgh Company: Surgeon-Captain D. Hepburn to be Surgeon-Major. The Glasgow Companies: George Henry Edington to be Surgeon-Lieutenant; Matthew Dunning to be Surgeon-Lieutenant.

South African War Notes.

The following have been discharged from hospital to duty —Major C. W. Allport, R A.M.C., and Civil Surgeons Charles Seymour Langley, Frederick Charles James, John Harry Saunders, Leonard Bostock, and Edward Albert Nathan.

No change is reported in Lieutenant Bean of the New South Wales Medical Staff

Civil Surgeon Wilbond is reported improving.

Civil Surgeon Donald Graham is reported dangerously ill with enteric fever (Rietfontein West, June 10th).

Colonel Baker, R A M C., and Civil Surgeons T. H. Gardner, E Archer Brown Cotterell, Robinson, Johnson, Bruce Hodge, and Hott are on passage home.

Major H. J. Wyatt, R.A M.C., and Major A. Wright, R A.M C., have arrived in England from South Africa.

The French Medical Service during the Recent Operations in China.

IN a supplementary report, which is published in the *Archives de Médecine Navale* for April, Dr. Mercié, principal medical officer in Chinese waters, gives an able and outspoken account, from a medical point of view, of the events which took place in the north-east of China during June, July, and August, 1900 Commencing with Admiral Seymour's relief expedition, which he characterises as "a brilliant feat of arms" and in which France was represented by 163 sailors under Captain de Marolles, with Dr. Autric in medical charge, Dr Mercié proceeds to give a graphic description of the state of unpreparedness in which his department found itself on the outbreak of hostilities. As late as May, and even up to the first days of June, no one believed that the Chinese would fight. The ease with which the Japanese had triumphed over them in 1895 completely masked the situation. The fact that since then the Chinese arsenals had been filled with modern arms was apparently ignored, and it was the universal opinion amongst all nationalities on the spot that nothing could induce Chinese soldiers to behave with courage and tenacity. But in spite of all this optimism it was not long before wounded and sick men began to arrive in comparatively overwhelming numbers. There were six French men-of-war on the spot, but Dr. Mercié was nevertheless put to his wits' end to find suitable accommodation for the patients. In eloquent terms he describes the shifts he was put to, thus completely bearing out the strictures of Dr. Léo to which we recently referred,[1] but although the executive officers gave him every assistance the utmost he could do was to provide beds for 60 of the worst cases. In addition to these there was also a sick list about 90 strong, and owing to the paucity of medical officers Dr. Mercié was compelled to attend to both categories single-handed. The way the patients had to be distributed in different parts of the *D'Entrecasteaux* made the task of looking after them trebly arduous, more especially as the insuffiency of trained medical attendants was equally lamentable. It is true that Captain Jan-Kerguistel, who was in command, was willing to detail orderlies from among the crew, but as Dr. Mercié remarks "it is not the first comer who can fill the rôle of an *infirmier*." Whenever, between dressings, Dr. Mercié wanted to wash his hands he had to walk and to climb at least 100 metres, in this way wasting several hours each day. Altogether the picture represented is that of a capable man struggling against well-nigh insuperable difficulties. But happily, when things were at their worst there was help forthcoming from an unexpected quarter. On July 7th the *Hakuai-Maru*, a Japanese Red Cross hospital ship arrived upon the scene and was placed at the disposal of the sick and wounded of all nationalities. The installation for 200 patients is described by Dr. Mercié as irreproachable in every respect. The staff comprised four medical officers, 33 male and 11 female attendants, all being specially trained and most efficient. "I may add, *en passant*," says Dr. Mercié, "that the hospital ships belonging to other powers, which reached Taku a long time afterwards, were reserved strictly for the sick of their own nationalities, and that the Japanese alone accepted patients without distinction." In conclusion Dr. Mercié draws a moral which might well be taken to heart by the controllers of other navies as well as his own. "It is of the utmost urgency," he says, "that hospital ships should form an inalienable portion of every sea-going squadron. In a naval engagement the improvised accommodation on board the *D'Entrecasteaux* would not have been available. A horrified world would have seen a return to the barbarous practice of a bygone age, when the unfortunate wounded men were heaped up *pêle mêle* in the dark unwholesome depths of the vessel until merciful death came to relieve them from their sufferings"

The Report on the War Office.

The report of Mr. Clinton Dawkins's Committee on War Office organisation is an important document and of a sufficiently drastic nature to be welcomed by that body of army reformers who have never seen anything good in our military administration. But how has the present state of things been brought about? Well, it is no doubt partly attributable to our party system of government. As one political party succeeds another changes are introduced, details get added or altered, new regulations are made and superimposed one upon the other until the machine gets more and more clogged, and almost ceases to act as a going business concern. While admitting all this and the shortcomings which the South African war have brought to light it cannot, we think, be denied that there is nevertheless no other nation which could have done what has been done in equipping, transporting, and landing such a force in that country. It says much for the personal capacity of the officials at Pall Mall that they have kept the machinery going so long and managed the affairs of the army as well as they have done. As the committee point out, the general structure of the organisation has been "built up piecemeal" and as the result of constant changes and compromises. The recommendations of the committee mainly deal with business principles and seem to be in the right direction, but we have yet to see how these are to be applied and how they will work out in the concrete and in practical business detail. There is nothing in the report of the committee so directly affecting the army medical service as to lend itself to comment, but we sincerely trust that a place will be found in any scheme for its being duly considered and properly represented.

The Parkes Memorial Prize.

Captain H. A. Howell, R.A.M.C., has, as we have already announced, been awarded the Parkes Memorial Prize for an essay on Venereal Diseases in British and Native Armies. This prize, which consists of 75 guineas and a bronze medal, is awarded every third year to the writer of the best essay on a subject connected with hygiene. The competition is open to the medical officers of the army, navy, and Indian services, of executive rank on full pay, with the exception of the assistant professors of the Army Medical School during their term of office. The subject for the next prize will be "On the Prevention of Disease amongst Armies engaged in Active Operations in the Field, with Special Reference to the Sanitary Organisation of a Field Force," to be illustrated as far as practicable from the personal experience of the writer. Essays must be sent in to the secretary of the Parkes Memorial Fund, Royal Victoria Hospital, Netley, on or before Dec. 31st, 1903. Each essay should have a motto and should be accompanied with a sealed envelope bearing the same motto and containing the name of the competitor.

The Royal Naval Hospital, Plymouth.

The First Lord of the Admiralty (the Earl of Selborne) and the other Admiralty Lords made an official inspection of the Royal Naval Hospital, Plymouth, on June 4th. Their lordships were received by Sir Henry Norbury, K.C.B., R.N. (Naval Medical Department), Inspector-General J. F. Fisher, Deputy Inspector-General C. C. Godding, and Deputy Inspector-General H. T. Cox. Many improvements are being made in the hospital. To each block of the building improved bath and lavatory accommodation is being added and the old wood floors are being removed and fire-proof concrete substituted. Since the previous official visit the new isolation buildings have been completed, the laundry extended, and new machinery added. A small building adjoining the hospital is to be enlarged and converted into a new block.

The Bestowal of the South African Medals.

The medical arrangements in connexion with the ceremony of bestowing the South African war medals upon the recipients on June 12th were under the supervision of Captain W. A. Ward, R.A.M.C. Twelve squads of regimental stretcher-bearers were distributed among the troops and two dressing stations were formed, one at the Tylt Guard-room, Horse Guards, to receive cases from the north and east of the ground, and the other at the south-west corner of the parade towards Storey's Gate, where there were ambulance-wagons to receive cases from the south and west of the ground. A station was also formed at the parkkeeper's shelter in St. James's park facing the Horse Guards. Among the recipients of the medals were members of the Royal Army Medical Corps and the consulting surgeons and civilian surgeons who have returned from the seat of war.

The Military Station Hospital, Portsmouth, and the New Naval Barracks.

On Monday, June 10th, the military hospital at this station was handed over to the contractors for the new naval barracks as the site of the officers' quarters. A site has been secured on Portsdown Hill for the military hospital. The new naval barracks will occupy an area of 62 acres and barrack-room accommodation will be provided for 4000 men.

Ambulance Challenge Shield Competition.

The Ambulance Challenge Shield of the Volunteer Medical Association has been won by the 2nd V.B. Royal Fusiliers (City of London Regiment). The following are the names of the individual winning competitors: Corporal S. Bethell, Corporal C. Burridge, Private W. G. Tringham, and Lance Corporal P. J. Watkins.

Captain T. H. M. Clarke, D.S.O., R.A.M.C., has taken up his duties as private medical adviser to H.R.H. Prince George of Greece. Captain Clarke came prominently under notice during the time that he served in Crete.

The King has made the following appointments:—To be an Ordinary Member of the Third Class or Companion of the Most Distinguished Order of St. Michael and St. George: John Binny Hay, M.B., C.M. Edin., of the Gold Coast Medical Service, in recognition of his services in the siege of Coomassie To be a Companion of the Distinguished Service Order in recognition of his services during the recent operations in Ashanti Surgeon Captain William Fletcher, Militia Medical Staff Corps

Correspondence.

"Audi alteram partem."

HOSPITAL SUNDAY.

To the Editors of THE LANCET.

SIRS,—The approach of "Hospital Sunday" must be my plea for urging, as president and treasurer of the Fund, that the public should respond in a liberal spirit to the appeal which will be *made to them on* Sunday *next* in all the churches and chapels of the metropolis in behalf of the hospitals and dispensaries for the treatment of the sick poor This year the council have 201 institutions seeking to participate in the Fund The needs of all these charities, if *only to reimburse them for last year's outlay on the London* poor, would not be covered by £100,000

There is, happily, no necessity for me to enlarge upon the merits of these institutions their readiness in relieving those who are afflicted, the benefits they confer on the more fortunate by checking the *spread of disease*, and their success in mitigating the exceptionally sad consequences of illness when combined with poverty

But I desire to point out the unique character of this annual collection and the opportunity which it affords for unostentatious and practical *sympathy* with a cause which is Christian and self sacrificing beyond dispute Every inhabitant of the metropolis, irrespective of creed, is offered the privilege of easily gratifying his instinctive sympathy with the suffering poor , he is not subjected to pressure and of imposture there can be no fear

Should any of your readers be absent from public worship *or not in London next Sunday they may remit* their contributions to me at the Mansion House

I am, Sirs, yours faithfully,
FRANK GREEN, Lord Mayor.

The Mansion House, London, June 11th 1901

PS —I have just received a further generous donation of £10,000 from Mr George Herring who in his letter says "I hope your receipts this year will make a record one, as the hospitals and convalescent homes are greatly in need of funds, and it must be true charity to help our poor through *sickness to health* "

"DENTISTRY AND THE SERVICES"

To the Editors of THE LANCET

SIRS,—The very temperate and sensible annotation on the above subject in THE LANCET of June 8th has *tempted me to* point out what appears to be a possible method of dealing with the teeth of our soldiers The present war has conclusively demonstrated that legislation is necessary Sending four dentists to South Africa to relieve the sufferings of our soldiers shows that the Government realises its present responsibility, but such a course of action in no sense deals with the question upon a permanent footing Although it is surrounded with many difficulties it seems possible to avoid pitfalls *and to bring into force a system that shall* adequately deal with it which not being too expensive a luxury might be within the pale of practical politics The problem can be dealt with as follows 1 The appointment of dental surgeons at all the large military depôts who shall be at the service of the troops at home The question of payment is one that can be arranged 2 That all army medical men shall upon admittance *into the service be required to receive six* months' training in operative dentistry at a dental hospital and shall be required to produce evidence of attendence upon such a course 3 That each army surgeon shall be provided with the necessary equipment to enable him to *treat all ordinary dental troubles*

I have purposely avoided entering into minute details which could be carefully thought out and arranged, but it would seem desirable that a permanent Government official should be appointed to see that the scheme is efficiently carried out I believe the adoption of a course such as is here suggested would permanently deal with a difficult subject

I am, Sirs, yours faithfully,
MORTON SMALE
June 1901

ARMY MEDICAL REORGANISATION.

To the Editors of THE LANCET

SIRS,—Unless this *subject* be *tabooed I would* like *to call attention to the important* bearing of the last return from the War Office, giving the total losses in the field force in South Africa to the end of May, on the professional status of the *personnel* which the medical staff requires In this return the total death loss from war injuries is placed at 5592 and that from *disease* at 9667, while no less than 49 761 were *invalided, doubtless* mainly from disease and especially enteric fever—a preventable malady, and of these 342 had died and 2864 been discharged the service as unfit, the remainder having recovered and been returned to duty except 819 still in hospital This return is much on a par with the former ones, both in respect to this and former wars and to the experience of other nations, and illustrates the enormous ravages which disease makes, both as to temporary inefficiency of the field force and also as to permanent loss from deaths or discharges from the service from unfitness so brought about, and brings prominently to the front the nature of the duties which devolve on the medical staff (in peace as in war)—sanitary, medical, surgical, in relative importance as placed—and the necessary professional qualifications of the members composing it if these highly important duties bearing on army efficiency are to be effectively carried out And the pressing question in the near future is *the degree to which these essentials will find expression in the* conclusions of the committee to which the completion of the work of the South African Commission is to be entrusted No mere "readjustment of the apparatus' or organisation, however otherwise complete, "can compensate for defective *personnel*," and unless a thoroughly efficient body of professional men well qualified in these respects can be obtained for the Royal Army Medical Corps and more power be given to it to make its influence operative in the army sphere for good, it is not apparent how the future can be an advance over the past No doubt other qualifications of an administrative and military character are also necessary in this corps to which such multiple duties are entrusted, and should receive consideration , but the figures above mentioned indicate beyond all doubt that its true basis is *primarily and essentially professional*, a feature which does not seem to me to figure in its right proportion in the schemes advanced for the reorganisation of the corps other than in the original recommendations of the South African Commission To obtain *men* of a *good professional* status is a *sine qua non* if this corps is to be made fitted for its duties, and to retain each executive rank at a high standard is no less essential ; and no less essential are these professional qualifications for the administrative grades for it is apparent that no proper inspection and supervision of the work of juniors can be made nor proper confidential reports for the guidance *of those controlling selection can be* furnished unless the administrating seniors possess the necessary ability and knowledge on which to act

With a department organised on a military framework as the Royal Army Medical Corps now is the danger of not giving adequate expression to its right professional basis is apparent , in the past, except as a recommendation of the Crimean Commission it has received no consideration , and in the future, unless there be a strong professional element in the constructive committee that is to be, it is difficult to perceive how it is to obtain the recognition it requires—as of paramount importance, as illustrated in the *figures* of the War Office return referred to

I am, Sirs yours faithfully,
FRANCIS H WELCH, F R C S Eng ,
Surgeon Colonel A M S (retired)

Lee S E., June 10th 1901

SURGICAL OR MEDICAL TREATMENT IN GASTRIC ULCER?

To the Editors of THE LANCET

SIRS,—The very interesting article by Mr C B Keetley which appeared in THE LANCET of June 8th, p 1597, on a series of cases of gastric ulcer demonstrates in a very clear manner the value of operation in the greater number of those cases where hæmorrhage is persistent and profuse and where ulceration has existed for a prolonged period. But I am not quite at one with Mr. Keetley in the conclusion which is to be gathered from his summing up, that, broadly speaking, all cases of gastric ulcer should be operated on as soon as the diagnosis is assured, for it is by no means uncommon to have severe and frequently recurring hæmorrhage from the stomach of a patient, and yet when operation has been decided on and the stomach opened into the ulceration has proved so extensive (though superficial) that no radical treatment can be attempted, and, save for the benefit of washing out the viscus, the use of the knife is abortive. A case illustrative of this came under my care some little time back in Fremantle Hospital, Western Australia, a few notes of which I will quote. The patient was admitted to hospital on Feb. 4th, 1900, suffering from anæmia and hæmatemesis. Vomiting immediately after food was experienced and there was great pain in the epigastrium. The pulse was small and rapid and the temperature was 99°F. On the 5th the copious hæmorrhage from the stomach continued, the temperature was 101°, and the pulse was thready and very weak. A quarter of a grain of morphia was ordered to be administered every four hours, no food or liquids by the mouth being allowed. The bowels were opened by a soap and-water enema and towards evening a mixture of peptonised milk, virol, and brandy was injected into the bowel. On the 6th no great improvement was shown to have taken place so operation was decided upon. The patient took the chloroform well and the stomach was exposed and opened near the greater curvature, an incision of one and a half inches being made. The wall was natural in appearance from the outside though a good deal of venous bleeding occurred in making the incision. The interior was congested and in some places it was superficially ulcerated, but in no part had the ulcerative process extended beyond the mucous membrane. A stream of weak boric acid solution was used to wash out the detritus and pieces of blood coagulum, the wound in the stomach was closed with a close row of Lembert sutures, and the operation was completed in the usual way. Six hours after the operation a hypodermic injection of digitalin and morphine was given, and a couple of quarts of tepid water per rectum did much to relieve the intense sensation of thirst. The patient had a good night. On the 7th teaspoonful doses of tepid water every 20 minutes were ordered. Two rectal enemata of milk, brandy, and virol were administered at 2 P.M. and at 6 P.M. There was a good deal of retching which was relieved soon after the administration of the digitalin and morphine hypodermically. There was no hæmorrhage or actual vomiting. On the 18th there was much retching. Two hypodermic injections of morphia and digitalin were given at 8 A.M. and 4 P.M. The wound was examined and was found to be doing well. On the 10th the patient was quite free from pain and retching and was feeling hungry. Rectal enemata only with water by the mouth were employed. On the 12th a tablespoonful of chicken jelly was given twice during the day by the mouth, and two tablespoonfuls of peptonised milk were given every four hours. The rectal feeding was continued. On the 15th the stomach held liquid food readily, a pint of strained beef-tea and two pints of peptonised milk with two tablespoonfuls of virol being taken in the 24 hours. On the 20th beaten-up eggs, custard, boiled rice, semolina, &c., were added to the diet. On the 25th a little minced chicken was taken, the patient was gaining strength rapidly, but the recumbent position was still insisted upon. From this date the progress of the case was uneventful, but the patient was not dismissed from hospital until six weeks after the date of admission.

Another case, on all fours with this one so far as primary symptoms were concerned, came under my observation some months later and was treated from a medical standpoint only by prolonged rest in bed, absolute avoidance of food by the mouth for a fortnight, and a steady but watchful administration of digitalin and morphine hypodermically. The results were highly satisfactory, the patient being sent out of hospital in three weeks' time quite recovered.

Many lives are undoubtedly saved by timely operation in this grave pathological condition, but it must be admitted that at least as many more run unnecessary risk by too early an interference, when even the most appalling hæmorrhage can be satisfactorily controlled by keeping the organ at perfect rest and by the judicious use of morphine and digitalin till the blood-pressure falls.

I am, Sirs, yours faithfully,
L. WHEELER, M.B., B.Ch. R.U.I.,
Surgeon, Fremantle Hospital, Western Australia.
Junior Conservative Club, Albemarle street, W., June 10th, 1901

PRELIMINARY MEDICAL EDUCATION.

To the Editors of THE LANCET.

SIRS,—As it seems possible that the negative given to Dr. McVail's resolution yesterday may be construed to affirm that the Council was satisfied "that the courses of study in the subjects of the first professional examination are in all cases sufficient," I think it right to state that so far as my vote and that of most, if not all, of those who formed the majority went, it was not intended to convey any such interpretation. I felt bound to vote against the resolution, because it withdrew from the Council the main question involved by the recent action of the London Colleges—namely, their ignoring the resolution of the Council *requiring five years' study at a recognised medical school*, and their consequently ceasing to require a certificate of registration from candidates for their licence. These, and not the standard of education, were the fundamental questions before the Council, and had Dr. McVail's resolution been carried all reference to these important questions would have been shelved. Further, Dr. McVail announced that the vote on that resolution would be final, so that not alone was no expression of opinion possible on these points, but no alternative course other than complete submission by the Council to the decision of the Colleges was possible. I seconded Mr. Ball's amendment because I consider that some arrangement which would place all the licensing bodies on an equality is most advisable; and while not pledging myself to details I consider the principle underlying that and Mr. Bruce's motion the best, not alone for licensing bodies, but for the advancement of medical education; for I am of opinion that when possible it is desirable that both physics and chemistry should be taught as subjects of preliminary education. I am, Sirs, yours faithfully,

LOMBE ATTHILL, M.D Dub.
General Medical Council Office, Oxford-street, London, W.,
June 11th, 1901.

CÆSAREAN SECTION IN LONDON.

To the Editors of THE LANCET.

SIRS,—In your "Mirror of Hospital Practice" for June 8th, p. 1604, it is stated that "from 1886 to 1894 22 cases [of Cæsarean section] were recorded in the London Hospital." Will you permit us to say that this is erroneous, that no such number of Cæsarean sections have been either performed or recorded in the London Hospital during the period mentioned?

We are, Sirs, yours faithfully,
G. E. HERMAN, } Obstetric Physicians to
ARTHUR H. N. LEWERS, } the London Hospital.
June 8th, 1901.

⁎⁎⁎ We willingly publish this letter. It must have been obvious to every reader that the statement referred to was incorrect. The words "the" and "hospital" were interpolations owing to a printer's error. The reason of the error is clear; the case upon which we were commenting occurred in the London Hospital. The sentence should have read, "from 1886 to 1894 22 cases were recorded in London."—ED. L.

"LOCAL *v.* GENERAL ANÆSTHESIA IN CERTAIN CASES OF ABDOMINAL SURGERY."

To the Editors of THE LANCET.

SIRS,—Your correspondent, Dr. S. Johnson Taylor, finds fault with me for limiting my remarks on Mr. Morse's article to a particular question. My objection to Dr. Taylor's contribution is just the contrary, that he is leaving the point particularly raised by Mr. Morse and broaching the whole subject of what inconveniences and dangers attend general anæsthesia and whether a local anæsthetic can obviate these.

This is too large a question to discuss in your correspondence columns; my letter was to controvert a definite position of Mr. Morse's when he placed general anæsthetics in the first place as causes of shock in certain operation cases. I endeavoured to show that this is not justified by experience and that a properly selected and administered general anæsthetic is more likely to diminish than to increase the chances of shock. I am, Sirs, yours faithfully,

Sloane terrace Mansions, S.W. J. BLUMFELD.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Effect of Famines on the Population of India.—The Decline of the Plague Epidemic.—The Coming Monsoon.—Decrease of Typhoid Fever in Military Stations.—The Kasauli Institution.—The Success of the Victoria Memorials.—Flagellar Fever in Malignant Tertian Malaria.

DURING the past 10 years it is estimated that the population of the whole of India has only increased by 28,000,000—a rate considerably less than that of the previous decade. There are only two factors which can have an appreciable effect on the number of the people. A diminished birth-rate may have contributed to this lessened increase, but its influence cannot have been very great. At the outside 20 per cent. may be put down to this cause. An enhanced mortality must be the chief factor. It is estimated that there were 20,000,000 more deaths than under ordinary circumstances there should have been, and if we put 1,000,000 deaths down to plague there remain 19,000,000 which can be attributed with some reason either to actual starvation or to the diseases arising therefrom. It is impossible to know how many people have suffered from the famines of the past few years. A further increase in the numbers under famine relief has recently occurred and the total now requiring help is 312,169. These facts speak for themselves.

The plague epidemic shows a still further decline. The total number of deaths returned for last week is 2592, against 3298 in the previous seven days. The improvement is general. In Calcutta there were only 134 deaths and in Bombay city there is a decline also. By the recent census the rate of mortality for the past week in Calcutta is 34 5 per 1000, but if calculated on the previous census it would have been 42 per 1000. In Bombay city the death-rate is 89 11 per mille calculated on the old figures of population, so that as the inhabitants have decreased in number the actual rate should be even higher. Cholera and small-pox being less than normal this extraordinary mortality has to be accounted for. There were only 375 deaths attributed to plague (out of a general mortality of 1357), which would, if deducted, still leave the rate of general mortality about 60 per 1000.

It is anticipated that the monsoon will occur earlier than usual this year. The conditions in the Indian Ocean from the Seychelles and Zanzibar show more rain and wind and are distinctly favourable. For some months past the rainfall in East Africa and Upper Egypt and the Soudan has been above normal and several storms have occurred in the Arabian sea. All these occurrences are said to be indications of an early and favourable monsoon for India. The rain-bearing current on the Bombay side and into Upper India may be adversely affected if snow-giving depressions come from the direction of Persia. The recent heavy snowfall in Chitral and the consequent high barometric pressure in Upper India caused some anxiety. It is the west of India where the famines have already occurred to which the uncertainty of the monsoon chiefly applies.

The reports from the various military stations in India continue to show a much smaller percentage than usual of typhoid fever cases. This is in all probability explained by the absence of drafts from home and by the retention of more or less seasoned soldiers. It must not be hastily assumed that the dangers of typhoid fever have been to any great degree lessened.

The Kasauli Institution continues to receive more and more recognition and support. A native gentleman has now come forward and presented a 16-roomed house in the bazaar for the accommodation of pauper native patients. There have now been 230 patients treated by Pasteur's antirabic method since August last and interest in the institute is evidently spreading in native society.

The All India Memorial to the late Queen Empress continues to receive widespread support. The total amount of subscriptions is now close on 34 lakhs of rupees—equal to over £220,000. The Victoria Scholarship Fund for training native midwives is also flourishing and the total sum received to date is 3½ lakhs of rupees.

Major Buchanan of Nagpur has recently published in the *Indian Medical Gazette* some important observations on exflagellation of the malarial parasite. He says that exflagellation does take place before the blood is drawn and he is thus opposed to the views of Manson and Celli. He describes three stages. The first or primary fever in which rings are found. The second period (after the primary fever) during which there is little or no fever, but in which there is a marked diminution of ring forms with an increase of crescents and at the end a few flagella bodies. The third period or flagella fever having a tertian appearance characterised by the rare presence of ring forms but by first increasing and then decreasing crescents and the presence of increasing and decreasing flagella bodies. The primary fever, he says, "is caused by the sexual sporulation of the rosette forms; the interval occurs at the time when the crescents are maturing. The secondary fever then comes on, and although it is contrary to the view held by Manson, Celli, Ross, Christy, and others, still we believe that this part of the fever is caused by the breaking-up of the crescents, or, in other words, that exflagellation does occur inside the body."

May 16th.

Rapid Decline of the Plague Epidemic.—The Continued Famine.—The Re-organisation of Municipal Health Departments.—The Education of Sanitary Inspectors.—The Health of Calcutta in 1900

THE plague mortality throughout India continues to decrease rapidly. The returns for last week show a total of only 1918 deaths against 2592 in the preceding seven days. The improvement is general. Bengal returns 464 deaths against 758 the previous week; Calcutta 79, against 134; Bombay Presidency, 547; Bombay city 295, against 310; Madras Presidency, 9; Punjab 247, against 341; North-West Provinces 164, against 306; Karachi 154, against 289; Mysore, 21; and Kashmir, 28. On the basis that 100 deaths a week constitute an epidemic, as against the occurrence of so-called sporadic cases—a standard which has come somehow or other generally to be adopted—the epidemic in Calcutta is reported as having ended. The outbreak is thus calculated to have lasted for 16 weeks this year, as compared with 23 weeks last year.

Since my report last week on the increase of the numbers under famine relief I hear that the labourers thrown out of employment by the completion of the harvest operations are beginning to crowd to Government relief works in the famine area of the Bombay Presidency. There has been this week an increase of 30,000. In the native States increases are also reported and the total number under relief throughout India is now 418,046.

The municipality of Calcutta is waking up to its duties with regard to sanitary matters. A re-organisation of the engineering and health departments is in contemplation. It has been recommended by a sub-committee (1) that the conservancy department should be amalgamated with the engineer's department; (2) that the building department should be a separate department with a responsible officer in charge; (3) that the city should be divided into districts, each district being self-contained in the health, building, and engineering items; and (4) that a local municipal office should be established in each district which should be the centre of the municipal business for the district. This scheme is something like that adopted in Bombay, but it contemplates a much greater decentralisation of work and of powers. I have already reported upon the proposed sanitary improvements for every ward of the city.

The great want of Indian cities seems to be in properly educated sanitary inspectors Something has been done to endeavour to supply this want by the Sanitary Commissioner of Madras and recently by the Bengal Government in offering scholarships to certain engineering students. I am glad to see that this matter is also being taken up by the new health officer of Bombay who has recently drawn up regulations for the examination and instruction of candidates for these posts. He includes in his subjects elementary physics and chemistry in relation to water, soil, air, and ventilation; elementary statistical methods; municipal hygiene, including sanitary defects in and about buildings, water-supplies, sanitary appliances, drainage refuse removal and disposal, offensive trades, disinfection, and food inspection; and in addition the Bombay Municipal Act Statutes and the orders, memoranda, and model by-laws in force. This is a matter which might well be taken up also by the University of Calcutta. A movement has been recently on foot to establish a department of hygiene. In addition to granting certificates and degrees to medical men it might well institute a course of study and an examination for sanitary inspectors.

The health of Calcutta in 1900 has been recently commented upon by the Inspector-General of Civil Hospitals for Bengal. The past year has been an exceptionally unhealthy one. The death-rate of Calcutta rose to 53 88, and that of Howrat to 60 50, per 1000 There was an increased mortality from all the principal diseases. Plague undoubtedly was the chief factor in the increase, but the extraordinary rainfall in September caused a great mortality from cholera and diarrhœal complaints. The plague inspections at the port of Calcutta involved the examination of over 250,000 persons and the disinfection of the clothing and bedding of 79,255 persons. Small-pox was more prevalent than usual and 74 per cent. of the patients admitted to hospital were unprotected by previous vaccination. These figures show the inefficient state of vaccination in the city and the Lieutenant-Governor has animadverted strongly on the imperfect enforcement of the vaccination laws. Cholera also was more prevalent and the death-rate in the hospitals rose to 63 94 per 1000. There were 8354 deaths from plague, and of the 449 patients admitted to hospital 357 died, giving a death rate of 79 51 per cent. This is about the same rate as occurs in the hospitals in Bombay. The various medical institutions of the city seem to be carrying on their work satisfactorily, but in one hospital there appears to be some evidence of overcrowding and the Campbell Hospital is said to suffer from the municipal refuse depôt and loading platforms being too adjacent.

May 25th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Banquet to Major Ronald Ross, F.R.S., late I.M.S.: The Fifth Expedition to West Africa Organised by the Liverpool School of Tropical Medicine.

MAJOR RONALD ROSS and the members of the expedition sailing on Saturday, June 15th, under the auspices of the Liverpool School of Tropical Medicine, were recently entertained at a banquet given by Mr. Alfred L. Jones, the chairman of the school. The guests included the Lord Bishop of the diocese, the Lord Mayor, Surgeon-General R. Harvey, C.B., D S.O., Director-General I.M S., Sir Edward Russell, and Principal Dale of University College. The chairman, on proposing "Success to the Expedition," said that the school was engaged in one of the greatest works ever attempted—viz., the endeavour to establish in the tropics the possibilities of healthy life as existing in temperate climates. They had accomplished much, and he gratefully acknowledged the sympathy which they had met with, both from the public and the press. These expeditions to West Africa had awakened public interest in a great question. They had also taught people in the tropics the possibility of combating malaria. He eulogised the work done by Major Ross in this direction and warmly congratulated him on his election to the Royal Society. He also had to announce that the Colonial Office had given instructions that the expedition was to have every facility for carrying out its work. Major Ross, in reply to the toast, said that he felt that night to be one of the proudest in his life. He had the honour to respond to the toast; he had received the honour of election to the Royal Society; and he sat between his present chief, Mr. Alfred Jones, and his former chief, Surgeon-General Harvey, and in company with his old tutor, Professor E. Smith. The expedition did not—he was glad to say it—consist solely of himself. It would include others who had helped this work on. In that respect he acknowledged his indebtedness to Mr. Alfred Jones, who had said that he would give the expedition enough plaster to cover Africa; to Mr. John Holt for his liberal gifts of oil; and to many others, including the manufacturers of various patent materials for killing insects. The expedition was not going out to prove the mosquito theory. That had been conclusively proved three years ago. It was a matter of absolute certainty, which was only doubted by amateur pathologists who were prepared with confidence to deny what was now accepted by every scientific man in Europe. They were going not to prove the theory but its applicability. They might not be able wholly to exterminate the mosquito, but he was satisfied from six years' study of the subject that they could reduce its numbers to one-tenth or even one-twentieth. He had, he was glad to say, funds sufficient to employ from 30 to 40 native assistants for one year and it would be their duty to clear Freetown (to begin with) of mosquitoes by filling up puddles, emptying tanks of water, and fumigating houses. Once that work had been carried out the municipal authorities would only need to keep it up. The experiment would go on for 10 years. In that time they hoped to work down to Accra and Cape Coast. The Bishop of Liverpool, in an interesting speech, said that commerce and science would go hand in hand. The time had passed when science could despise commerce as mercenary and material while commerce looked down on science as visionary. This School of Tropical Medicine was an instance of the results that might be expected from an alliance of the two. The school was in its infancy, but it had already moulded heroes prepared to carry the blessings of science to the ends of the earth.

Death of Mr. Thomas Cayzer, M.R.C.S. Eng., L.S A.

Mr. Thomas Cayzer died at his residence at Grassendale on May 29th, after a short illness, in his sixty-seventh year. Mr. Cayzer enjoyed an extensive practice in the outskirts of Liverpool, and was widely respected by a large circle. He took a great interest in the Volunteer movement, and at the time of his decease was Surgeon-Lieutenant-Colonel in the 6th Lancashire Volunteer Artillery. He had also obtained the Volunteer decoration. To quote the words of a lay contemporary, "The corps has lost a worthy and most respected officer, whose sole idea was to do his duty to his country, to his corps, and to his fellowmen."

Hospital Extension at Wallasey: Local Government Board Inquiry.

Dr. E. P. Manby, Local Government Board inspector, held an inquiry at the public offices, Egremont, on June 3rd, respecting an application by the Wallasey Urban District Council to borrow £15,500 for the purpose of hospital extension for infectious diseases. The existing hospital was built 20 years ago, and then consisted of one pavilion containing eight beds, an administrative block, and a laundry. In 1894 an additional pavilion was erected to accommodate 12 beds and a small addition was subsequently made to the administrative block. The population of the district was now 53,000, an increase of 20,000 in the last decade. The proposed scheme included the erection of an additional 24-bed pavilion and a reconstruction and enlargement of the administrative block. With the addition of the 24-bed pavilion, the accommodation would provide 44 beds, and the site would ultimately accommodate two 24-bed pavilions and one eight-bed pavilion. The building would consist of a centre three-storey block, with the greater portion of the present administrative block as a wing to the east. A similar wing, providing additional bedrooms on the first floor and other accommodation on the ground floor, would extend to the west, but it would not be necessary to build this wing for several years. An engine-house, a new disinfector, as well as certain sanitary accommodation, were also included in the scheme, and the whole of the building would be fitted up with the necessary electric bells and telephones, as well as with the electric light. The extension, there can be no doubt, is urgently required, as during the late epidemic of scarlet fever it was no uncommon thing to find three or four people occupying a ward which was only intended to accommodate one person.

Hospital Saturday Ladies' Street Collection.

On June 8th the ladies made their annual street collection on behalf of the Hospital Saturday Fund. The city was divided in 85 sections, controlled by 47 heads of districts, each having a staff of workers, in all numbering close upon 1000. The day was summerlike, in fact all that was desirable for a favourable collection. Last year £837 12*s.* 4*d.* were contributed in the same manner, and it is confidently expected that a substantial increase will result from the effort of last Saturday.

The Bootle Town Council and their New Medical Officer.

In consequence of the death of Mr. R. J. Sprakeling the post of medical officer of health of the borough of Bootle has become vacant. At the recent meeting of the Bootle Town Council the chairman of the Health Committee moved the adoption of a motion altering the conditions of service in the appointment of medical officer of health. The late medical officer was not debarred from private practice, but now, owing to the increase in the number of inhabitants in the borough, the Health Committee were of opinion that the time had come when the medical officer should devote his whole time to his corporate duties. The recommendation included a proposition that the medical officer of health should also perform the duties of visiting medical officer of the Linacre infectious hospital as well as those of surgeon to the police force and the fire brigade, at a salary of £350 inclusive. Exception was taken by several members of the council to the grouping of the offices which is certainly contrary to the general usages of other corporations. Moreover, it was pointed out that the council could not possibly expect a medical man who had spent the best part of his life in acquiring a special knowledge of public medicine to take up the three positions for such a small remuneration. After further discussion it was resolved to raise the salary from £350 to £400, and with this alteration the orginal recommendation was carried. The Mayor made a sympathetic allusion to the late Mr. R. J. Sprakeling who had occupied the position of medical officer since the incorporation of the borough.

Complimentary Dinner to Civil Surgeons who have served in South Africa.

It is intended to recognise the services of the local medical men who have served as civil surgeons in South Africa by a complimentary dinner to be held at the Exchange Station Hotel on June 20th. Mr. Edgar Browne, the President of the Medical Institution, will preside on the occasion. The movement is warmly supported by Sir William M. Banks and other prominent local practitioners.

June 11th.

WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Cardiff Infirmary.

THE mayor and corporation, the members of the Cardiff Medical Society, and the members of the board of management of the infirmary, with their friends, were invited to the opening of the new operating theatre by Mr. Edmund Owen on June 6th, and nearly 300 ladies and gentlemen responded to the invitation. The proceedings were of a very enthusiastic character and Mr. Owen delivered an ideal address for such an occasion, the picturesqueness of his description of the Good Samaritan being appreciated to the full by his audience.

Superannuation of a Poor-law Medical Officer.

At the end of last year the board of guardians of the Swansea Union decided to re-arrange the district for which Mr. D. Howell Thomas had been for many years medical officer and to appoint in his stead a medical officer to the workhouse who should give his whole time to his duties. Mr. Thomas resigned his appointments upon the understanding that he should have five years added to his term of service. At the last meeting of the board this addition was made so that Mr. Thomas is now entitled to full superannuation allowance.

Refusal to fill up the Census Schedule.

The enumerators employed in taking the recent census do not appear to have met with many downright refusals to give the necessary information to the officials. One such instance occurred at Pilney, in Gloucestershire, where a man of somewhat pronounced views flatly refused to give to the enumerator, the district registrar, or the superintendent registrar the particulars that the law required of him, stating that he considered it unnecessary and quite a mistake upon the part of any Government to take a census. The Registrar-General very properly gave instructions for this pronounced individualist to be prosecuted and he was fined £2 15*s.* 6*d.* It was stated during the course of the magisterial proceedings that the defendant was himself an enumerator at a previous census.

Taunton and Somerset Hospital.

The Taunton and Somerset Hospital was established early in the last century and the present building, in which there is accommodation for 100 patients, is quite out of harmony with the requirements of the present day. The governors have decided therefore to make very extensive alterations at a cost of £6500, towards which sum £3500 have already been promised. The principal alterations involve the enlargement of some of the wards with the re-arrangement of the sanitary offices, the removal of the kitchen to an upper floor, the provision of a hand lift and a lift for patients, the erection of a new block of 12 bedrooms for nurses, and the provision of external iron fire-escape staircases, together with a general renovation of the whole building.

The late Mr. Thomas Bond.

Much regret is felt in the west of England at the sad death of Mr. Thomas Bond in London. The deceased was a member of an old Somerset family and was accustomed to visit his native county during his holidays. He was well known as a follower of the Devon and Somerset staghounds, with which pack of hounds he hunted regularly every season.

Sanitary Matters in Glamorganshire.

At the meeting of the Sanitary Committee of the Glamorgan County Council held on June 7th the medical officer of health drew attention to the sanitary condition of Gilfach where, he stated, the sewage was discharged into ditches, then into the river. An epidemic of diphtheria with 20 deaths out of 118 cases had recently occurred there. The local district council had shelved the whole question of drainage and the provision of an isolation hospital. The committee decided to inform the local authority that unless they remedied the present state of affairs the county council would interfere.

June 10th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Glasgow University.

THE preparations for the ceremonies which are to mark the occasion of the ninth jubilee are now fully completed. Numerous distinguished guests and delegates have arrived in the city and everything promises that the arrangements will prove worthy of so distinguished and interesting an occasion. From to-morrow until the end of the week there will be an academic holiday and the students will be free to entertain their *confrères* from other universities and to take their part in several of the larger ceremonies. To-night they conduct a torchlight procession as a welcome to the foreign delegates. At the graduation ceremony which is to be held on June 14th numerous honorary degrees are to be conferred. The recipients for the most part will be distinguished delegates representing foreign and other universities and various learned societies and corporations. There are, however, to be some honorary graduates whose claim to recognition stands on a different basis. Prominent among these will be Mr. Andrew Carnegie who is to receive the degree of LL.D. The senate have also resolved to confer the same degree on Mrs. John Elder of Govan and on Mrs. James Campbell of Tullichewan. It is to these ladies that the University mainly owes the establishment and equipment of the Queen Margaret College for Women Students. The College buildings and grounds were presented by Mrs. Elder who also, at a cost of £12,500, founded in the University the chair of Naval Architecture, and gave a donation of £5000 as an additional endowment to the chair of Civil Engineering. A third lady, Miss Agnes Weston, who has so long and successfully devoted herself to the amelioration of the condition of the British sailor, is also to receive the honorary LL.D. degree. The fund for the extension and better equipment of the University continues to make progress. The total amount now reaches nearly £44,000. Amongst recent donations is one of £5000 from Mrs. Nathaniel Dunlop, one of £250 from Mrs. Paul Rottenburgh, and a similar sum from Mr. D. M. Stevenson.

Glasgow Royal Infirmary.

The proceedings in connexion with the reconstruction scheme have unfortunately not yet ceased to excite controversy. The action of the committee in setting aside the decision of the architectural expert (Dr. Rowand Anderson) whom they had summoned to their aid was much criticised at the time, but as in their recent statement the committee explained that the assessor's opinion in opposition to the selected scheme was not based on any failure in regard to vital or essential particulars, but mainly on a difference of opinion in respect of style of architecture and elevation, it was hoped that public confidence would be content with their judgment. Dr. Anderson has, however, written to the press strongly controverting the committee's statement. He asserts it to be entirely wrong to lead the public to believe that his rejection of the design in question rested solely on a question of architectural treatment. On the contrary, he affirms that he attached supreme importance to the qualities demanded in a building to be utilised for the scientific treatment of the sick and injured. The compliments bestowed by the committee upon the architectural and æsthetic virtues of the scheme they have adopted Dr. Anderson describes as rank nonsense, and with some vigour protests against "the ghastly absurdity of a baronial infirmary."—Dr. James Allan has been appointed physician to the infirmary in succession to Dr. John Dougall whose term of office has expired.

Proposed New Hospital for Consumptives near Aberdeen.

Designs have been prepared by Mr. George Coutts, architect, Aberdeen, for a proposed new wing for 16 phthisical patients at the Convalescent Cottage Home, Newhills, near Aberdeen, which is supported by voluntary contributions. There will be separate kitchen, dining-room, and sleeping accommodation, and every facility according to the best continental models will be afforded for open-air treatment. As soon as the funds permit a water-supply by gravitation will be introduced.

June 12th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Ulster Medical Society.

THE annual meeting of the Ulster Medical Society was held on June 6th in the Belfast Museum, the President, Professor W. H. Thompson, M.D., R.U.I., being in the chair. The reports presented showed that there are now 152 members of the society and that there is a balance in hand of £69 1*s.* 6*d.* The following office-bearers were elected for session 1901–1902 :—President: Professor Whitla, M.D., R.U.I. Vice-Presidents: Dr. C. Shaw and Dr. James Colville. Treasurer: Dr. John McCaw. Secretary: Dr. Robert Campbell. Pathological secretaries: Dr. J. Lorrain Smith and Dr. T. Houston Librarian: Dr. R. R. L. Leathem. Council: Dr. H. L. McKisack, Dr. W. Calwell, Professor Byers, Dr. W. B. M'Quitty, Professor Lindsay, and Dr. A. Dempsey.

Holywood Dispensary.

Dr. W. Donnan has been appointed medical officer of Belfast Urban No. 14 and Castlereagh No. 2 dispensary district in place of Dr. S. H. Dunlop (Holywood) resigned.

Irish University Education.

The latest pronouncement on this question is that of the Presbyterian Church in Ireland, which at the meeting of their assembly in Belfast on June 7th passed resolutions in favour of non-sectarian public education, as best adapted to the circumstances of Ireland, and against the establishment and endowment out of the public funds of a Roman Catholic university. A very strong resolution was also passed protesting against the appointment of a Royal Commission on university education in Ireland from whose inquiry Trinity College and Dublin University are to be excluded, and calling upon all the Unionist Members of Parliament in Ireland to resist any such appointment. Some of the speakers went the length of suggesting that the assembly should not appear before the Commission if Trinity College was excluded. There is still no announcement of the persons who are to act on this Commission; indeed, on June 7th Mr. Balfour said in the House of Commons, in reply to an inquiry, that he was sorry he could not give the names.

County Armagh Asylum Board.

At a meeting of the Committee of Management of this asylum on June 10th the report of the inspectors was submitted. It stated, *inter alia*, that owing to the lack of records it seemed quite impossible to fix the amount of the deficiency or the extent of the misappropriation of asylum stores which it was feared had taken place. The new system of keeping accounts only came into operation on April 1st, 1900, but it appeared that the keeping of the former records had been grossly neglected, a fact which even the most casual examination would have disclosed. Regarding the functions of the committee it was their duty to see that the institution was properly managed and to see that the resident medical superintendent acquitted himself of his duties; and although they could not be expected to supervise the daily working the inspectors felt assured that to appoint a sub-committee to visit the asylum and to associate themselves with the management would be of the greatest benefit. They trusted that as new and satisfactory appointments had been made to the posts of clerk and storekeeper, and as the resident medical superintendent fully realised his responsibility such a state of affairs would not again be possible.

Chronic Lunatics in Workhouses.

The question—a confessedly difficult one—of how to deal with chronic lunatics, of whom there are now 4000 scattered about in the various union workhouses in Ireland, is being a good deal discussed at present. How to maintain and treat these poor creatures, who are not dangerous to themselves or others, is being debated by county councils (who really are the rating authorities), by boards of guardians (in whose workhouses there are a large number of these chronic cases), and by the asylum boards who find their institutions over-crammed with patients. There are several courses open to a county council in dealing with this problem which affects both workhouses and asylums: (1) they may build a separate auxiliary asylum for chronic harmless lunatics, with a resident medical superintendent and at least one assistant medical officer; (2) they may add to an existing asylum buildings less elaborate than the original ones in the form of a new department to be placed under the care of the resident medical superintendent of that asylum; and (3) they may acquire and adopt some workhouse or other building either as a separate auxiliary asylum or as a department of some existing asylum. By an amalgamation of unions they might free some existing workhouse for the purpose of an auxiliary asylum. The Local Government Board have put these various courses before the county councils and they are now making inquiries as to what may appear possible in the way of amalgamating unions. The initiative rests with the county councils and of course it depends largely on local considerations which of the courses indicated is taken, having regard both to the welfare of the unfortunate people concerned and to the interest of the ratepayers. It is doubtful, at least in some cases, whether the erection of buildings specially fitted for the reception of chronic lunatics might not be cheaper in the end than the adaptation of the old ones originally built for a different purpose.

The late Physician to the Queen in Ireland.

Probate has been sealed in London of the will of Dr. William Moore, late physician to the Queen in Ireland. The personalty was sworn at £38,500, and the sole executor is his eldest son, Mr. William Moore, M.P.

June 11th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

An Institute of Colonial Medicine.

AN active campaign is being waged at present with a view to the creation in Paris of a school of colonial medicine. Professor Raphael Blanchard is at the head of the movement, and a public subscription has been started for the inauguration and endowment of the new institute. Already nearly 250,000 francs have been subscribed. Only recently M. Brouardel and a delegate of the French Colonial Union had an official interview with the President of the Paris Press Syndicate so as to obtain the aid of the press. A manifesto has been issued to the public, signed by M.

Berthelot, M. Brouardel, M. Gréard, M. Perrier, and M. Roux, in order to help the subscription lists. The manifesto points out that the recent extensions of the French colonial possessions have imposed upon France a new moral responsibility, both as regards the peoples who have recently come under her rule and also as regards Frenchmen who exile themselves in those far-off regions. Finally, it must *not be forgotten that returned colonists may import new* diseases into France. As a matter of fact, the special education given to medical men who may find themselves brought into contact with tropical disease is insufficient. The medical men employed in the colonial service are drawn from the following sources: (1) ordinary civilian medical men who learn nothing during their course of study about tropical medicine; (2) naval sanitary medical officers, a class dating from 1896, who are appointed after a very elementary examination and who in the great majority of cases do not possess that knowledge of tropical pathology which is necessary for the right understanding of disease; (3) military medical officers who neither at the Lyons schools nor at that of Val de Grace have ever studied tropical pathology; (4) naval medical officers from the Bordeaux school who during their six months practical course at Toulon attend twice a week a course of bacteriology and a theoretical course of tropical pathology; and (5) colonial medical officers, also from the Bordeaux school, who after they have received their doctorate are passed by a practical school (*école d'application*) without any preparation and can be sent out to serve in the colonies with only a very slight knowledge of tropical hygiene and pathology. All the same the promotors of the new enterprise are rather too much disposed to argue that there does not exist even the embryo of colonial medical teaching. At the Faculty of Bordeaux M. le Dantec, a professor *agrégé*, holds extra classes in tropical pathology. At the school of Algiers M. Brault holds the chair of tropical diseases to which are attached a certain number of beds at the Mustapha Hospital for the purpose of clinical teaching. At Marseilles the Municipal Council supports five chairs for special teaching. Both at Bordeaux and at Marseilles the wish is expressed that the new institute should be started in one or other of these two towns, and it would seem only reasonable that one of the large French ports should be selected for the purpose. They have hospitals in which are met cases of tropical diseases, so that they can be studied with their results under the eye of the student and it is difficult to understand why a desire should exist for the institute to be in Paris, where cases of tropical diseases are hardly ever seen and where colonial medical officers have no reason to live. Nevertheless, the committee of the Faculty of Medicine has passed a resolution to the effect that a course of instruction in tropical medicine and hygiene should be begun by the Faculty and attached to the already existing chairs of hygiene and medical natural history. The latter chair at present deals with nothing but parasitology. The committee of the Faculty of Bordeaux has passed an almost identical resolution with the addition of creating a new diploma—namely, one in colonial medicine. The course for this diploma will last three months and will include practical and clinical work as well as theoretical studies. The work will be supervised by the staff of the faculty and the total expenses will not exceed 200 francs. At present, then, Paris, Bordeaux, and Marseilles are at daggers drawn, but it is obvious that either in Bordeaux or Marseilles there are much greater facilities for teaching and organisation than there are in Paris. In Paris the whole system would have to be started as something new; the expenses would be heavy and in addition expenses would be imposed upon naval or colonial medical officers for residence, for as a class they do not live in Paris. The Paris Faculty of Medicine, however, has made the question one of personal *amour-propre* on account of being at the head of French medical schools and also perhaps because it wishes to use the occasion as a means of rebutting the accusation so often made that it is a reactionary body and opposed to all progress.

The New Director of the Assistance Publique.

The successor to the late lamented M. Napias has been appointed. He is M. Mourier who has hitherto been employed on the administration of the Conseil d'État and who, *ex-officio*, was member of the Conseil de Surveillance of the Assistance Publique. Political considerations have, as is always the case in France, determined this appointment. The new director is not a medical man, and report says that he holds very decided views in opposition to the medical staff of the Assistance, the encroachment of whom he deplores and the members of which he holds responsible for the unfortunate financial condition of the Assistance. He has already announced his intention of inaugurating great reforms, but all his predecessors have started with this programme. Political exigencies have, however, always stood in the way of the realisation of these schemes and time only can show whether the new director will fare any better.

The Responsibility of Asylum Proprietors.

The First Chamber of the Civil Tribunal of the Seine has just given judgment in the case of the proprietor of an asylum at Fontenay sous Bois, named Duchamel. He was condemned to pay 10,000 francs damages to the parents of a neurasthenic young lady who hanged herself in the closet. The Tribunal based its judgment on the grounds that there must have been gross negligence on the part of those whose duty it was to look after the patient. She, as everyone responsible in the asylum knew, had already made two attempts at suicide and finally succeeded in hanging herself with the aid of a strip of stuff which she had in all probability cut off from her sheets.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Inhalations of Oxygen.

A PAPER on Inhalations of Oxygen has been read before the Berlin Medical Society by Dr. Aron, who said that the atmosphere contained a sufficient proportion of oxygen to saturate the hæmoglobin of the blood, and as the hæmoglobin when saturated was, of course, unable to absorb more oxygen inhalations of oxygen were evidently useless. To obtain a more abundant absorption of oxygen it would be necessary to bring a greater quantity of hæmoglobin into contact with the air either by stimulating the circulation or, in cases of anæmia, by increasing the quantity of hæmoglobin in the blood, or by deeper respiration. Dr. Aron then explained that the statement of Professor Pflüger that in ordinary respiration one-fifteenth of the hæmoglobin remained unsaturated had no practical significance. Dr. Aron had found that the results of experience were in accordance with his theoretical views. The few instances in which the patients felt relieved by inhalations of oxygen were cases of dyspnœa in cardiac or pulmonary diseases but the improvement was maintained only while the inhalations were actually in progress. In bronchiectasis and in growths of the mediastinum there was no effect at all and the same was the case in chlorosis and anæmia In one case of cardiac disease an embolism of the pulmonary artery followed the inhalations. In no instance was there a marked decrease of cyanosis. Inhalations of oxygen had also been recommended as a treatment for apparent death from drowning and for poisoning by morphia, but artificial respiration was just as efficacious. In poisoning by carbonic oxide and in rarefied air where the amount of available oxygen was less than in the normal atmosphere the administration of oxygen was advisable. Dr. Aron had found that in animals in which he had produced artificial dyspnœa the administration of oxygen was not followed by any perceptible influence on the circulation.

Specialists in Germany.

The *Deutsche Medicinische Wochenschrift* of June 6th contains an interesting article by Dr. Heimann on the specialists of Germany. As far as I know, this is the first time that statistics of the number of specialists and the proportion of them relatively to the general practitioners have been collected. The title of specialist not being an official one may be assumed by any medical man and it is matter of common knowledge that there are specialists practising for the most part in large towns whose special training consisted in a course of six weeks' duration at Vienna or even only at some polyclinic at home A good many of these so called specialists combine general practice with their specialty. Dr. Heimann's article is not based on official records which, of course, do not exist, but on the information supplied by the respective medical men and published in Dr. Schwalbe's medical directory. It shows how large the number of specialists really is, for of 27,374 medical men in Germany no less than 3431 described themselves as such. There was one medical man to every 2014 of the population of the empire and one specialist to every 16,068 of the population. In Saxony there were no less than 370 specialists among 2048 medical men, the proportion thus being 1 : 5·5. The majority of the specialists, of course, resided in the large towns with more than 100,000 inhabitants, the number being 2068, or 60·3 per cent. of all the specialists; in the towns of medium size, with from 45,000 to 100,000 inhabitants, there were 512, or 14·9 per cent. of the whole, and in small towns with less than 45,000 inhabitants there were 851, or 24·8 per cent. of the whole. It might appear strange that so many specialists resided in small towns—but these latter included several university towns, with many professors and *privat-docenten*. Moreover, a great number of sanatoria, asylums, &c., were situated in small towns or in the country. Of the large towns, Stuttgart had relatively the greatest number of specialists, the number being 73, and their proportion to the general practitioners being 1 : 2·6; in Hamburg, where there were 107 specialists, the proportion was 1 : 5·2; in Berlin it was 1 : 6·4. Altona had relatively the smallest number of specialists, the total number being seven and the proportion to the general practitioners being 1 : 13·1. With regard to the classification of the several specialties it was found that 609 were ophthalmologists, 534 practiced surgery, 533 were obstetricians and gynæcologists, 516 were specialists for diseases of the ear, the nose, and the larynx, 485 for mental and nervous diseases, electrotherapy, &c., 269 for internal diseases, 224 for diseases of the skin, 134 for diseases of children, and 127 for genito-urinary diseases. In Berlin, where there were 493 specialists, 47 devoted themselves to internal diseases, 58 to mental and nervous diseases, 75 to diseases of the ear, &c., 58 to diseases of the eye, 66 practised surgery, 10 were orthopædic surgeons, 46 were specialists for genito-urinary diseases, 36 for syphilis and diseases of the skin, 77 for obstetrics and gynæcology, and 20 for diseases of children.

Operations for Gastric Ulcer.

Professor Korte lately read a paper before the Verein für Innere Medicin on the Surgical Treatment of Gastric Ulcer. He said that the principal indication for operation was stenosis of the pylorus with dilatation of the stomach as a sequel of cicatrised ulcers; operation was also sometimes indicated in open ulcers of the pyloric or præpyloric region, when the pain was very severe and could not be relieved by internal treatment. Other indications were small but repeated hæmorrhages, profuse hæmorrhages, perigastric adhesions, and perforation of the stomach. In perforation, owing to the imminent danger of peritonitis, an operation must be performed as soon as possible and not later than 12 hours after the perforation had taken place. In the other cases—viz., in stenosis with dilatation, hæmorrhages, &c.—the indication was not so absolute as it was in perforation. The dangers to be anticipated depended on the nature of the case, on the general state of the patient, on the size and position of the ulcer, on its adhesions, &c. Some of the immediate dangers of the operation, such as infection of the peritoneum and giving way of the sutures, might be diminished by the adoption of improved methods, but there still remained a liability to complications over which the surgeon had no control, among which might be mentioned pneumonia, embolism, and hæmorrhage from open ulcers. Notwithstanding these dangers an operation must not be postponed too long, as in an exhausted patient the risk became, of course, much greater. Professor Korte has performed operations on 38 patients with gastric ulcers; in 17 cases there were open ulcers and in the remainder there were cicatrices. All the patients had been ill for a great while, some of them for as long as 20 or 30 years, and all of them had undergone protracted internal treatment. Their general condition was bad and they complained of gastric pains and vomiting. In 18 cases there was hæmatemesis; in 32 cases there was stenosis with dilatation, the seat of the stenosis being as a rule the pylorus; in one case, however, it was in the duodenum, in five cases in the præpyloric region, and twice in the middle of the stomach. Apart from stenosis operations were performed once for profuse hæmorrhage, 10 times for perforation into the peritoneum, and six times for perforation into the subphrenic tissue. With regard to the methods of operation, resection ought to be performed only when there were no adhesions and when the case was suspected to be one of cancer. In five circular resections one death occurred. Gastro-enterostomy was performed 29 times with a mortality of 20·6 per cent. In one case complicated with stenosis of the œsophagus gastro-enterostomy was combined with gastrostomy. Hacker's method was exclusively used without a Murphy's button, and only one pyloroplasty was performed. One patient had to be operated on for profuse hæmatemesis, a ligature was put on the bleeding artery and it seemed as if he might recover, but after a week he died from renewal of the hæmorrhage. Nearly all the patients operated on for perforated ulcer showed the symptoms of peritonitis. The operations were performed, as a rule, from 20 to 24 hours after the perforation had taken place, the result being that out of 10 patients only one recovered. In the discussion the views of Professor Körte were received with approval by Professor Ewald, Professor Rosenheim, Professor Fraenkel, and other speakers.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Society for the Study of Malaria.

THE Minister of the Interior has placed the sum of 5000 lire at the disposal of the Society for the Study of Malaria as a contribution towards the expense of the prophylactic measures which they intend to adopt during the approaching malarial season; and the King himself has set a good example to all large land-owners in malarious districts by providing a sum of 10,000 lire to be employed for a similar purpose on his estate of Castel Porzano, where it will be remembered Dr. Sambon and Dr. Low carried out their successful experiment last year. The society have provided stations for study in the provinces of Udine, Verona, Vicenza, Padua, Ravenna, Pisa, Basilicata, and Siracusa, in addition to those already established in the provinces of Rome, Milan, Cremona, Mantua, Ferrara, Foggia, and Lecce. A special effort is to be made for the protection of the agricultural population against malaria. A prophylactic experiment on a large scale will be made along the Emilian coast; and, indeed, in all the malarial districts the authorities are exerting themselves in preparing for a vigorous anti-malaria campaign during the coming season. In the city, and especially in the Campagna of Grosseto, a careful series of prophylactic experiments from which valuable results are expected has been in progress for some time. The measure of success which has already attended the efforts of the society has led some foreign Governments, including those of Spain and Portugal, to apply to it for information as to the best methods of carrying out an efficient prophylaxis against malaria.

Sanatorium for Tuberculous Children.

The birth of the new Italian Princess has been made the occasion for a handsome donation by the King of 200,000 lire (£8000) to the Commune of Rome towards the erection of a sanatorium for tuberculous children.

Malaria and Typhoid Fever.

The record of cases in which malaria and typhoid fever have co-existed in the same individual is not yet an extensive one; or, rather, the cases in which a thoroughly reliable diagnosis has been made are not numerous. At a recent meeting of the Lancisian Society of Rome, Fiocca, who is known for his accurate investigations in connexion with Widal's reaction, reported an indubitable instance of this combination. The patient, who had never previously suffered from illness, paid a visit on Oct. 4th to Leprignano; on the 15th he was attacked with malarial fever and was admitted to the Hospital of St Giacomo, where he remained until apparently cured till the 30th of the same month. He then returned to Leprignano, but was again taken ill and had to be re-admitted to the hospital on Nov. 25th suffering from a fever which continued till Dec. 28th with symptoms of typhoid fever, the blood giving a positive Widal reaction but showing no malarial parasites. After the latter date followed six days of complete apyrexia, and then, on Jan. 4th, another attack of malaria, with the presence of æstivo-autumnal parasites in the blood, which soon yielded to quinine. On the 10th the temperature again rose, ushering in a relapse of typhoid fever which continued until Jan. 22nd, when another period of apyrexia followed lasting nine days On Jan. 31st came another relapse, this time of malaria Again quinine was employed with good effect, since which time the patient has kept quite well. Here, then, were present simultaneously the infections both of malaria and of typhoid fever, the former detected by the parasites found in the blood, the latter by the agglutination reaction of Widal which was obtained at different periods and varied in intensity from a dilution of 1 in 50 to one as high as 1 in 500. It would appear in this case that there was a tendency for the two diseases to keep themselves distinct and independent; when one ceased the other, after a short interval, began. This alternation could have been due only in part, if at all, to the action of the quinine which was not administered in sufficient doses till after Jan. 15th.

Medullary Anæsthesia.

As surgeons become more familiar with the effects of medullary anæsthesia the evidence grows that as at present practised—namely, with injections of cocaine or its derivatives—the method has certain very distinct drawbacks which render its general use objectionable Bier himself who introduced the method is of this opinion after an experience of over 1200 cases Lugli, who has operated at the hospital of S. Giacomo on 75 cases, noted as immediate after effects formication in the lower limbs, a sense of weight there, or the feeling that the limbs themselves were entirely gone, pallor, retching, more or less obstinate vomiting, sweating, depression of spirits, acceleration of the pulse with diminution of arterial pressure, occasionally vertigo, involuntary emissions of fæces and of wind from the bowel, tremor more or less intense and diffused, and pain at the seat of injection. As later effects he observed headache, usually frontal, sometimes occipital, lasting not more than two days and mostly slight; increase of temperature for not more than from two to three days, generally moderate, but once or twice rising to 102° or 103° F.; rarely vomiting; very rarely vertigo and temporary difficulty in micturition; and frequently pain in the lumbar region and near the point of injection. The later disturbances are of no importance, but the effects immediately following the injection, though usually transitory, are sometimes exceedingly severe In three cases they were of the gravest and most alarming description, and in one they were attended with a fatal result This last was in a man, 60 years of age, with a hernia which had been strangulated, and perhaps gangrenous, for over three days, the subject besides of sclerosed arteries, emphysema, and generally in a condition of great gravity, enough, perhaps, of itself to have led to the unfortunate issue The quantity of cocaine was 16 milligrammes (about a quarter of a grain) and death took place after four hours

Professor Albertoni of the University of Bologna.

Professor Pietro Albertoni has now been for 25 years a medical teacher, and the completion of this long term of academical work was on May 31st made the occasion of an interesting ceremony Professor Albertoni took his degree at the University of Padua in the year 1873, and three years later, at the age of 27 years, he was nominated Professor of Physiology at the University of Siena In 1878 he removed to the University of Genoa, where he received offers of chairs in several universities, and eventually he proceeded from Genoa to the University of Bologna as Professor of Pharmacology and afterwards of Physiology, which latter subject he is still teaching. Among his numerous original investigations mention may be made of his work on the functions of the cerebellum, on the action of sugars in the body, and on the food of the Italian peasantry. His scientific pursuits, moreover, have not prevented him from taking part in politics and public life, for he is a Member of Parliament for his native Lombardy and a town councillor of Bologna A numerous company was present at the ceremonial of May 31st, and the mayor offered him the congratulations of the town which is proud to own him as a citizen He was presented by his pupils with a gold medal, the obverse of which shows his head surrounded by a laurel-wreath; on the reverse is the following inscription: "A Pietro Albertoni; I discepoli; Siena, 1876—Bologna, 1901." He was also presented with an artistically illuminated address, accompanying a volume of treatises by several medical men who have worked in his laboratories The Medical Society of Bologna presented him with another gold medal which on the obverse bears emblems of medicine and pharmacology, with the inscription, "Societas Medico-chirurgica Bononiensis"; on the reverse:—

Petro Albertonio Gazoldiensi
Physiologiae tradendae munus
Annum jam quintum et vigesimum
Summa cum laude obeunti
Sodales medici
Anno MDCCCCI.

June 7th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

The Close of the Season.

THE Cairo season is now over and nearly all the hotels are shut except two large ones which cater for summer visitors In spite of the South African campaign and of the national mourning the season has been a fairly good one, for Egypt, instead of being visited by only a handful of Englishmen as was the case 20 years ago, has now become a winter resort for Americans, Germans, and many others. The Americans alone run special palatial steamers during January and February from New York to Alexandria *via* Italy, and though they never stay long in the country they spend their money freely to the great enjoyment of the hotels and bazaars As regards health the season has been exceptionally prosperous, for it is the first time since the beginning of the present pandemic that influenza has not been brought to us from England or America. There has therefore this year been no localised epidemic, small-pox has not been heard of among the visitors, and there have only been one or two cases of typhoid fever. Curiously enough scarlet fever, which is very rare in Egypt, has been present among some of the women and children of one of the Scotch regiments, and last summer the matron of a hospital where scarlet fever is quite unknown contracted the disease. It is difficult to know how these sporadic cases occur unless the infection is imported from England by parcel post.

Improved Steamers

By the new express steamers which carry the Indian mail from Brindisi to Port Said it is possible for patients to dine in London on Friday night and in Cairo on the following Wednesday. When these steamers were first started three years ago passengers complained bitterly of their vibration, but now the propellers have been altered and although they go at a pace of 20 knots an hour their motion is not unpleasant; in fact, in calm weather a sort of yachting excursion can be taken through the Greek Islands by Cephalonia, Ithaca, Sappho's Leap, and the Styx Their coal consumption is 120 tons per day, with 350 electric lights on board, and their mail capacity is 300 tons which represents every week 3000 bags, including 1000 for India, 800 for Australia, and 300 for Egypt, besides bags for China, Ceylon, and other places Another advantage of travelling by this route is that there are no Customs examinations between London and Egypt and a special train now runs down to Brindisi wharf close to the steamers Sometimes, as during this month when Italy is afraid of contracting plague from India, the steamer and even the train have to run through in quarantine and an Italian medical man accompanies the steamer so as to protect Europe from infection. The P & O. Company are obliged to pay him a fee of £1 per day. Mail steamers grumble at the vexatious quarantine laws, to which, however, they are obliged to submit One of their complaints is the delay which occurs at Suez As an instance of which they cite, the P & O. s s *Australia* which lately reached Suez at 6 25 P M , and pratique was refused because it was after sunset, so she could not enter the Canal until 9 A M next morning. This was especially hard as they had spent £250 in extra coaling in order to get mails and passengers quickly from Aden to Suez

Sanitary Department.

The budget has been increased this year by £3800, which allows provision for the appointment of European sanitary inspectors in Cairo, Port Said, and Suez These posts have hitherto been filled by natives who were practically useless. Dr Dreyer, a German bacteriologist, has now been appointed to Cairo, and Dr Baker, an Englishman, to Port Said. Another crying want has been remedied, for the minimum salary of native medical men has been raised from £72 to £96 per year. It is absurd to expect a trained medical man to be honest and respectable upon a small salary when he is surrounded by many temptations to increase it by unfair means which all his predecessors have employed for generations. Port Said has had no plague since last year's epidemic of May, June, and July, but a careful look-out has been kept for any new infection. Port Said is perhaps as much exposed as any other part of the world to the possibility of plague infection, for it is visited almost daily by steamers stopping to coal from India and China on the one side and Turkey and the Greek Isles on the other. An interesting experiment is being made by examining the rats of the town. All those caught in traps are kept for a week without being handled. If still alive at the end of the week it is assumed that they cannot possibly have plague and they are drowned and their bodies burnt. If, on the other hand, they die their corpses, under proper sanitary precautions, are sent for bacteriological examination and analysis. No plague has yet been discovered in the rats, but I mention it as it seems a very good method of discovering plague before it attacks human beings. The rat or the rat-flea theory of infection has been brought into prominent notice by Dr. Ashburton Thompson's report on the Outbreak of Plague in Sydney of last year. He believes, and gives reason for his belief, that the Sydney epidemic "was caused by communication of the infection from rats to man." Perhaps Port Said has never been so clean before in its life as it is now, for in addition to all plague precautions whitewashing has continued because of an outbreak of small-pox, and no less than 30,000 people out of a population of 43,000 have been vaccinated since the beginning of the year. These figures must be compared with the total vaccinations and re-vaccinations of 1898, which were 1558, and those for 1899, which were 1358. A disinfecting stove has now been given to Port Said which is used compulsorily by the natives and by the Europeans through the intervention of their consuls. There is as yet no infectious hospital, though this is a thing very much wanted. Port Said is distinctly improving in civilisation. There are now three hotels and a fourth is to be opened next winter. It seems to be generally recognised that Port Said is to be the future gate of Egypt, though the financial interests in Alexandria will probably continue to combat this view. In order to render communication easy between Cairo and Port Said it will be necessary for the Government to take over and to enlarge the existing railway line running along the Canal from Ismailia to Port Said, and this they will probably do when they succeed in coming to terms with the Suez Canal Company, to whom the present miniature railway belongs. A restaurant car has now been added to trains leaving Cairo for Alexandria, Ismailia, and Upper Egypt, so that travelling in Egypt is no longer a hardship.

European Hospitals in Cairo.

The so-called European Hospital, which was governed by the various consuls, has now been closed as being no longer necessary, for the leading nationalities have all found themselves in a position to erect a hospital of their own. The Germans and Austrians have for some years each had a hospital, while the Greeks and Italians are now about to build one. The French have just opened a very good hospital of 30 beds in the desert outside Cairo. The land was bought from the Government at the nominal rate of 1*s*. per square metre, and therefore only cost £600. The building has cost £6000 and it consists of 20 third-class beds the occupants of which pay from 2*s*. to 3*s*. per day; four second-class beds at 6*s*. per day; and six first class beds at 10*s*. a day. Besides this there are an up-to-date operating theatre and dressing-room for surgical patients, with two separate blocks—one containing four beds for isolation cases and one bed for possible lunatics and the other comprising kitchen, laundry, &c. The hospital is nursed by five sisters belonging to the well-known order in the East of St. Vincent and St. Paul.

Anglo-American Hospitals.

After some years of quiet deliberation the Anglo-Saxon community has now decided to build a private hospital in Cairo for their own needs and the Alexandria residents have at the same time come to a similar decision. In both cities a fund of about £9000 has been raised and a committee has been formed to raise more money and to decide next winter upon the purchase of land and the preparation of plans. At present English and American patients who cannot afford to pay the charges of nursing homes are dependent upon the hospitality of the German hospitals both in Cairo and Alexandria.

Cairo, June 3rd.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Reciprocity in Medical Practice in the United States.
